

Veiling and the Economic Integration of Muslim Women in France

Antoine JACQUET* and Sébastien MONTPETIT†

October 2024

Abstract

This paper provides the first empirical evidence on the economic costs of wearing the Islamic veil and on motives for veiling in a secular Western country. Using French observational data rather than small-scale interviews, we demonstrate a significant negative correlation between veiling and economic participation, even conditional on the respondent's religious environment. This newly-documented fact is not consistent with the existing economic theory of veiling in Muslim-majority countries, which has focused on the socio-religious signalling effect of veiling. We then show that a model which also accounts for reduced economic opportunities for veiled women is consistent with our findings in the Muslim-minority context. Using a structural interpretation of the model, we then disentangle the various motivations behind the joint decision to veil and to be economically active. Our findings indicate that veiled women are less economically active not due to religious preferences, but rather because veiling is costly on the labor market. Additionally, our results emphasize the significance of personal religious motives in the decision to veil, rather than signalling piety to others.

1 Introduction

In many Western countries, the Islamic veil is often perceived as a signal of both cultural distance from the majority, and of the subordination of women. It is a particularly burning issue in France, where state secularism (*laïcité*) “constitutes a pillar, even the identity and foundation of the community life.”¹ French secular policies regulating the veil in the workplace and in schools are thus founded on both gender-equality and secularism grounds.

Yet, as many politicians advocate for a strengthening of these policies, it is crucial to understand (i) the real motives behind veiling, and (ii) whether secular regulations would facilitate or pose obstacles to the economic integration of Muslim women. The economic theory of veiling proposed by [Carvalho \(2013\)](#) focused on the piety signalling effect of the veil. This theory suggests that policies which restrict veiling may have opposite effects, depending on whether veiling is mainly driven by women’s own religiosity or by the need to signal piety to their community. If veiling is driven by individual motives, then further restrictions on veiling may inhibit the socio-economic integration of Muslim women even more and reduce social welfare ([Carvalho 2013](#), [Shofia 2020](#)). If, however, veiling mostly acts as a social signal of a woman’s piety, then it might be an inefficient social norm arising from strategic communication concerns ([Bernheim 1994](#), [Bursztyn et al. 2020](#)). Another motive not explicitly modelled by [Carvalho](#), who focused on the Muslim-majority context, is the economic opportunity cost of veiling that Muslim women face on the labor market. For instance, in France, women who signal a Muslim affiliation to employers are known to have lower employment prospects ([Valfort 2020](#)). Can such economic motives account for the low economic participation of Muslim women? If so, policymakers who wish to foster their economic integration should focus their efforts on the multiple barriers they face in the workplace.

In Muslim-minority countries, most of the empirical evidence on veiling behavior remains based on interviews conducted over small samples of women (or adolescents). Moreover, in

¹[Andriantsimbazovina et al. \(2020\)](#), p. 7.

France, such interviews are typically conducted in the Parisian region, even though Muslims are increasingly present over the whole territory. In addition to this representativeness issue, this methodology has the inherent drawback that, especially for such sensitive topics, interviewees may be susceptible to social desirability bias. This is even more likely when respondents are aware that the topic of the interview is veiling behavior, which is frowned upon.

In this paper, we perform the first empirical analysis of the relationship between veiling and economic participation in a Muslim-minority country, using rich observational data with detailed information on religious practices. Our sample of more than 3,000 Muslim women constitutes the largest source of data on Muslim women and their veiling practices in France that we are aware of. In addition, its wide geographical coverage arguably improves representativeness compared to interview-based data. Using these data, we find that in France, veiling is associated with significantly reduced economic participation. Among Muslim women, the practice of always wearing a conspicuous religious symbol in public is associated with an economic participation (defined as being active on the labor market or studying) lower by 21.6 percentage points in the cross-section. This correlation is large and economically significant: in our preferred specification, it is equivalent to having an additional 1.2 children aged less than 4 years old. This negative relationship is robust to several sensitivity checks, including a panel analysis exploiting respondents' retrospective accounts available in the survey.

Other novel results concern the wearing of discreet symbols of religious affiliation (i.e. religious jewelry). We find that the correlation between discreet-symbol wearing and participation is *positive*. Furthermore, those symbols appear to be worn by Muslim women who are younger, educated, and moderately religious. These patterns suggest that in the French context, discreet symbols might play a similar role to that of the veil suggested by [Carvalho \(2013\)](#) in Muslim-majority countries.²

A second objective of this paper is to unpack the various motives for veiling. We develop

²We, however, have little statistical power to test this hypothesis because few Muslim women wear only discreet symbols in our sample.

a model to analyze the joint decision of veiling and economic participation. This provides a conceptual framework to understand the respective roles of religious motives (such as individual religiosity or signalling piety) and of economic motives (such as employment opportunities and on-the-job discrimination) in this joint decision. Our model notably nests [Carvalho's \(2013\)](#) seminal model of veiling. In our model, veiling is a response to individual and social religious incentives, acting both as a commitment device to follow religious norms and as a signal of the woman's commitment to her community. We build upon this theory to fit the French context, based on our descriptive results and on the ethnographic evidence. In addition to the religious incentives channel, we introduce economic incentives to (un)veil in the model, which reflect the documented barriers to economic participation that veiled women face. These two mechanisms have distinct implications for how the decisions to veil and to participate economically interact. According to the religious incentives channel, women should veil more when they participate in order to reduce religious costs of their social integration. On the contrary, the economic incentives channel suggests they should veil less because veiling reduces their economic opportunities.

We then take the model to the data to assess the relative strengths of these channels. Translating our conceptual framework into an empirical static discrete-choice model of veiling and economic participation yields testable implications for the two incentives channels, religious and economic. Within religious incentives, we also distinguish between intrinsic motives and social motives, leveraging the richness of the survey. For the social signalling motive, given that administrative data on religious diversity is not available in France, we develop new proxies. That is, we use the share of Maghrebi immigrants in the local population and manually digitize the local number and size of Muslim places of worship from another data source.

Our empirical findings are twofold. First, we find supporting evidence for the economic discrimination channel described in the theory, but not for the religious incentives channel. This result suggests that the primary reason why veiled Muslim women work less (or, equivalently,

that working Muslim women veil less) seems to be that veiling itself reduces their economic opportunities, and not that religiosity disincentivizes working. As such, the lower economic participation of Muslim women could be understood as a demand-side problem on the labor market, more than a supply-side one.

Second, we measure the respective roles of the different religious motives in the decision to veil. We find that a much larger share of the variation in veiling patterns can be explained by individual religiosity rather than signalling incentives. Our results thus question the rhetoric often used to justify policies restricting the wearing of religious symbols in France, which is the idea of a “silent majority” of Muslim women who are forced to wear the veil by their families or communities.

Related literature and contributions. This paper contributes to several strands of the literature. First, it provides novel empirical evidence to the vast literature on Islamic veiling in the social sciences.³ In this literature, most of the evidence is based on interviews with Muslim women since veiling behavior is rarely observed in surveys or other standard datasets. While interviews have the potential to dig deeper into specific questions of interest and uncover a large number of potential channels, they often suffer from small sampling and representativeness issues. In a recent contribution, [Shofia \(2020\)](#) measures the veiling rate at the district level to circumvent this problem and provides robust empirical evidence that better economic opportunities for women induce Indonesian women to veil. In contrast, in this paper, we study the case of a secular country in which Muslims form a minority and where wearing the veil is frowned upon rather than encouraged. Similar conclusions to that of [Shofia \(2020\)](#) were reached by [Aksoy and Gambetta \(2016\)](#), the closest study to ours, for the case of Turkey. [Aksoy and Gambetta \(2016\)](#) also attempt to study the determinants of veiling in a Western country, namely Belgium. However, they do not have a direct measure of veiling behavior, but rather a measure

³We review in detail the literature on veiling in France in Section 2. Recent contributions in other contexts include [Harrison \(2016\)](#) for the United States as well as [Aksoy \(2017\)](#) and [Aksoy and Gambetta \(2016, 2021\)](#) for Turkey.

of attitudes towards veiling in public. Moreover, the richness of our data allows us to further unpack the relative weight of various incentives that are difficult to measure in the decision to wear the Islamic veil over a large sample. In particular, we can distinguish between private and signalling incentives to veil, a question which has so far eluded empirical researchers.⁴

Second, we bring new evidence on motives for adopting costly cultural practices both theoretically and empirically. In the vast literature on the economics of religion and identity, it is now acknowledged that individuals may choose their identity via rational decision-making even if it requires costly investments or sacrifices (Iannaccone 1992, Akerlof and Kranton 2000, Atkin et al. 2021, Jia and Persson 2021). Though potentially rational, adopting (or transmitting) certain cultural practices can be an impediment to social and economic integration of certain groups. A strand of the literature has investigated the incentives that might justify such choices. Recent examples include foot-binding in China (Fan and Wu 2023), female genital cutting in Africa (Bellemare et al. 2015, Novak 2020, Gulesci et al. 2023), and baby-naming choice in France (Algan et al. 2022).⁵

We contribute to this literature in three ways. First, we document that in France veiling is associated with reduced economic integration of Muslim women, as opposed to the evidence from Muslim-majority countries (Aksoy and Gambetta 2016, Shofia 2020), and we provide detailed descriptive evidence of why Muslim women might wear such a costly signal of religious identity in France. Second, we rationalize this finding by adapting the theory of Carvalho (2013) to a Muslim-minority context, in which the expression of Muslim identity clashes with economic integration instead of facilitating it. Third, we uncover novel empirical patterns concerning the wearing of *discreet* symbols of religious affiliation, which have received little attention in the

⁴Another close study is that of Abdelhadi (2019) who finds that the wearing of the veil is associated with lower employment in the United States, but does not investigate the motives for veiling. Her result is consistent with our findings for France, for which we document large differences in economic participation between veiled and non-veiled women.

⁵There is also a relevant literature looking at incentives to abandon certain costly cultural traits and adopting less harmful ones. For example, Biavaschi et al. (2017) find important economic payoffs for the Americanization of migrants' names. See also Bisin et al. (2011, 2016) and Drydakis (2013) on economic returns of assimilation for migrants.

literature.

Third, our results have implications for State secularisation policies. Of particular interest in our context, two recent empirical studies reach opposite conclusions on the effects of the French headscarf ban in public schools. On the one hand, [Abdelgadir and Fouka \(2020\)](#) find that the 2004 ban depressed schooling outcomes of French girls of North-African origin.⁶ On the other hand, [Maurin and Navarrete-Hernandez \(2023\)](#) find that the 1994 ministerial circular asking school principals to prohibit the wearing of the veil in schools had a positive impact on their educational attainment. Even if they are comparing different cohorts of adolescents and different treatments, these contradictory pieces of evidence are puzzling. By focusing on why Muslim women are willing to sacrifice economic opportunities to veil, we offer a new perspective to this debate. Our empirical analysis lends support to the conclusions of the first study in that French secular regulations most likely inhibit social and economic integration of Muslim women.

The rest of the article is structured as follows. Section 2 provides the institutional context. Section 3 describes the data sources and provides a detailed descriptive analysis of veiling patterns in France. Section 4 outlines our theoretical framework. Section 5 translates this framework into an empirical model and covers its estimation. Finally, Section 6 concludes.

2 Historical and sociological background

The wearing of the Islamic veil has been a burning issue in France since at least three decades. In 1989, the “*affaire des foulards*” (headscarf affair) garnered nationwide attention when three girls were expelled from their middle school for refusing to remove their headscarves. The incident sparked heated debates but eventually culminated in the highest French administrative court ruling in favor of the expelled girls ([Scott 2009](#)). Despite this ruling, in 1994 the Ministry of Education issued a circular asking school principals to prohibit conspicuous religious symbols

⁶In a similar spirit, [Benzer \(2022\)](#) finds that the re-introduction of Islamic schools, which do not prohibit the headscarf, had positive impacts on girls’ educational attainment in Turkey.

worn by students. This controversial position was later enshrined in a 2004 law, whose supporters argued that headscarves “infringed on the liberty of conscience of other pupils and represented the triumph of communitarian pressures” (Abdelgadir and Fouka 2020 p. 4). The debate then shifted to other public spaces, with a nationwide ban of full-face veils (*burqa*) in 2010, and later with several city bans of the *burkini* in swimming areas and beaches.⁷

Despite the significance of these policies for Muslim women and girls, they have largely been excluded from the conversation. In fact, this “one-sided debate” has revealed a lack of understanding among policymakers about the realities and constraints faced by the Muslim population (Scott 2009, Nordmann 2004). Nevertheless, considerable research in sociology and anthropology has been dedicated to understanding the experience of Muslims in France, and particularly the reasons for women to wear the veil. In the following paragraphs we focus on two factors which have been shown to be significant in that decision: balancing religious and family expectations with societal integration, and the potential impact of veiling on economic participation due to discrimination.

Why do women veil? Secular policies against veiling in France have been justified by the idea of a “silent majority” of Muslim women who are forced to wear the veil by their families or communities. According to this idea, the benefits of helping this silent majority outweigh the harm imposed on other female Muslims who truly want to veil (Maurin and Navarrete-Hernandez 2023). However, existing evidence on the motives behind veiling behavior contradicts this argument. In fact, interviews and surveys conducted in France suggest that the vast majority of Muslim women who wear the veil do so by individual choice and not out of coercion (IFOP 2019, Institut Montaigne 2016). Even within the Muslim community, the motives behind veiling seem to be misinterpreted. For instance, non-veiled Muslim women are more likely to believe that veiling is done out of coercion or imitation (IFOP 2019). This discrepancy highlights a key

⁷The question of veiling in public resurfaced for instance during the debates surrounding the adoption of the “law on separatisms” of August 2021, with some Senators suggesting a complete ban of all religious symbols in public spaces (see Sénat 2021).

limitation of interview data: it is unclear whether “individual choice” reflects the preferences of the women themselves, or the internalization by these women of the preferences of their social networks.

In a series of interviews with Muslim girls and women,⁸ Gaspard and Khosrokhavar (1995) identified three broad categories of veiled women: “veiled immigrants,” i.e. middle-aged women who arrived in France veiled and kept the practice; adolescent girls born in France who wear the veil either by force or by choice; and young women who wear the veil willingly to reconcile their religious duties and integration into French society. The veil worn by first-generation immigrants is well tolerated by French society. Animosity is instead directed towards the veils worn by adolescents and young women born in France, which is perceived as a symbol of failed integration – “a sign of inherent non-Frenchness” (Scott 2009, p. 15).

When asked why they wear the veil, Muslim women mostly invoke religious duty (76%) and issues of safety (35%) (Institut Montaigne 2016). Young women in particular mention “the difficulty to reconcile their families’ demands with those of the society” (Khosrokhavar 2004 p. 90). Familial pressures typically discourage them from engaging in activities that favor their integration, such as going out with friends or finding a job. In this respect, veiling can be a tool which allows them to “exempt themselves from the constraints that traditionally weigh on women” (Gaspard and Khosrokhavar 1995, p. 37) and to resolve the tension between religious duty, families’ demands, and integration.⁹

This interpretation of veiling as facilitating integration is in line with research in economics which has explored veiling practices in relation to economic participation (Carvalho 2013, Shofia

⁸Gaspard and Khosrokhavar (1995) conducted around one hundred interviews with Muslim girls and women in the Paris and Dreux suburbs.

⁹ The following interview excerpts collected by Atasoy (2006) in Canada also illustrate this tension well:

“It is hard as a young woman not to have a boyfriend in this society. [...] The veil reminds you that this isn’t allowed [in Islam].”

Sarah believes the veil keeps her away from doing “stupid things like dating a guy.”

“The veil reminds me that I submit to Allah... If I don’t wear it, people might take it as I’m doing something wrong.”

“If you are not covered, you feel isolated from other Muslim girls. They don’t socialize with you. They think you are doing bad things.”

2020). The theory of [Carvalho \(2013\)](#) considers veiling as a technology available to Muslim women in order to alleviate the intrinsic and social costs of their integration. By providing a practical protection against opportunities to engage in religiously prohibited behaviors, veiling acts both as a commitment to oneself and as a signal of this commitment to others. This commitment aspect of veiling is confirmed by survey evidence and interviews conducted in France and elsewhere.¹⁰ Furthermore, [Shofia \(2020\)](#) provided evidence for this mechanism in a study of veiling among Indonesian schoolgirls.

Veiling and economic participation. The sociological and anthropological record documents the challenges faced by veiled women in France when trying to integrate into the workforce ([Adida et al. 2010, 2016, Jouili 2020](#)). Alongside the policies restricting religious expression in public areas, veiled women encounter various constraints in the workplace. For example, French civil servants have an obligation of religious neutrality – a strict application of *laïcité*, the French conception of state secularism. This obligation prohibits the expression of religious beliefs while on duty, including the wearing of conspicuous religious symbols. Breaching this obligation is considered a serious offense that can lead to sanctions or even dismissal.

Veiled women also encounter obstacles in the private sector. First, private-sector workers providing a public service are also subject to neutrality requirements. Second, since August 2016, private firms can introduce neutrality requirements in their internal rules of procedure. The law states that it is allowed “as long as these restrictions are justified by the exercise of other liberties and fundamental rights or by the necessity of the good functioning of the firm, and if they are proportionate to the pursued goal.”¹¹ Famous cases of firms who introduced neutrality requirements include a private kindergarten and a recycling factory. Third, studies have shown that Muslims, particularly those who display higher levels of religiosity (a trait associated with

¹⁰See for example [Atasoy \(2006\)](#) for Canada and [Read and Bartkowski \(2000\)](#) and [Droogsma \(2007\)](#) for the United States.

¹¹Law El Khomri of August 8, 2016. See <https://www.legifrance.gouv.fr/codes/id/LEGIARTI000033001625/2016-08-10>

wearing the veil), face discrimination when seeking employment. Using a correspondence-test method, [Valfort \(2020\)](#) demonstrates that while signalling religiosity increases call-back rates for Christian applicants, it significantly reduces them for Muslim applicants in France.¹² Similar discriminatory hiring practices have been reported in other European countries.¹³

Employers claim that discrimination against Muslims is due to religious expression causing conflicts, and accommodating religious practices is viewed as a challenge ([Adida et al. 2016](#), [Cintas et al. 2012](#)). Muslims, in particular, face discrimination as some of their religious practices, such as daily prayers and fasting, are perceived as reducing productivity ([Bouzar and Bouzar 2009](#), [Maillard 2017](#)).¹⁴ In its yearly surveys of French managers, the *Observatoire du Fait Religieux en Entreprise* documents a rise in observed religious behaviors requiring managerial intervention, with Islam being by far the most cited religion ([Institut Montaigne 2014–2021](#)).

Other motives. Of course, Muslim women report wearing the veil for various other reasons, including signalling piety to potential husbands, or even fashion ([Patel 2012](#)). Worth mentioning are identity motives that are not necessarily religious. For some Muslim women, the veil is a means to affirm their distinction with the rest of society and to feel closer to their community of origin ([Silhouette-Dercourt et al. 2019](#)). For instance, adolescents who want to distinguish themselves from their peers may use the veil as a visible sign of difference from the “rooted French” ([Khosrokhavar 2004](#), [van der Hasselt 2019](#)). In some cases, wearing the veil is a form of rebellion against a society that claims to defend liberty of choice but discriminates against Muslims, as evidenced by studies on “identity backlash” ([Abdelgadir and Fouka 2020](#)).¹⁵

¹²[Valfort \(2020\)](#) uses extra-curricular activities (volunteering for a Christian or a Muslim Scout association) as a signal of religiosity.

¹³[Weichselbaumer \(2020\)](#) and [Fernández-Reino et al. \(2022\)](#) also use correspondence tests to confirm the existence of discrimination against veiled women in Germany, the Netherlands, and Spain.

¹⁴[Hu and Wang \(2021\)](#) and [Nuryakin et al. \(2022\)](#) provide empirical evidence suggesting that Ramadan fasting does not in fact reduce productivity or students’ test scores, respectively.

¹⁵See also [Fouka \(2020\)](#) and [Sakalli \(2019\)](#) for evidence of cultural backlash against assimilation policies in other contexts.

3 Data and descriptives

In this section we start to explore empirically the relationship between veiling behavior and economic participation. We present our main data sources, and we describe them along several dimensions of interest. We first provide novel descriptive evidence on French Muslim women’s living conditions. The data suggest a strong negative correlation between veiling behavior and economic participation in this population.

3.1 Data

Our primary data source is the cross-section from the *Trajectoires et Origines* survey (henceforth TeO; [INED and INSEE 2008](#)). Conducted in 2008 by the French National Institutes for Demographic Studies and for Statistics and Economic Studies (INED and INSEE), the TeO survey targeted adults between 18 and 60 years old residing in metropolitan France. Purposefully oversampling immigrants and minorities, it includes 3,032 women who identify as Muslim, of which 3,003 have non-missing data on veiling behavior. To our knowledge, this is the largest sample of this kind in France.¹⁶ When including Muslim men and other religious groups, the entire survey contains more than 21,000 observations.

The TeO dataset is a comprehensive source of information on various aspects of respondents’ lives, including living conditions (such as employment, education, housing, commune of residence, and health), social life (such as migration history, language use, family, and children), and public life (such as political views, experiences of discrimination, and social relationships). Of particularly value for this study is the religion section, which is a unique inclusion in a French survey of this scale since the collection of individual information on religion is closely monitored in France. This section includes variables such as religious affiliation, measures of religiosity, religious symbols worn, and intergenerational religious transmission.

¹⁶Two surveys conducted by private firms, namely [Institut Montaigne \(2016\)](#) and [Institut Français d’Opinion Publique \[IFOP\] \(2019\)](#), have much smaller sample sizes (slightly above 1,000 individuals of Muslim origin, both genders included) and do not have a similarly deep content as that of TeO.

We also use the TeO survey to create a panel dataset of respondents’ lifetime education and labor-market status. The dataset is constructed by analyzing respondents’ retrospective accounts, year by year, of their work status including salaried work, self-employment, unemployment, studying, staying at home, inactive for other reasons, or out of metropolitan France.

Our second data source is the *Annuaire des mosquées de France* (La Boussole 2004), a comprehensive directory of mosques and Muslim praying rooms in France. This is a novel data source in the literature, which we digitized manually. Compiled by a Muslim association in 2003–2004, the directory provides for each worship facility at the time its full address and estimated capacity by gender.

3.2 Measurement

Alongside standard metrics of economic activity, our empirical analysis relies on measures of religious practice and of the individual’s religious environment which we describe here.

Veiling. We use the following question from the TeO survey:

In your daily life, do you wear in public a piece of clothing or jewelry that might evoke your religion? (1) *Never* (2) *Sometimes* (3) *Always*

If applicable, respondents were subsequently asked to report which religious symbols they wear. Answers were later sorted by the survey institute into four categories: Jewelry, Clothing, Headcoverings, or Others. Because they visibly signal religion and are the ones usually targeted by secular policies, we group the Clothing and Headcoverings categories together as *conspicuous symbols*. Among Muslim women this is an excellent proxy for veiling, since headcoverings represent 93% of these conspicuous symbols. In contrast, we group Jewelry and Other symbols, which can usually be hidden, as *discreet symbols*.¹⁷ We then cross these categories with the

¹⁷A respondent who wears both discreet and conspicuous symbols is categorized as wearing conspicuous symbols.

initial answer on frequency of wearing religious symbols. Thus, in our measure of veiling each respondent is categorized as wearing either (1) *no symbol* (if they answered *Never* to the initial question), (2) *sometimes discreet symbols*, (3) *always discreet symbols*, (4) *sometimes conspicuous symbols*, or (5) *always conspicuous symbols*.¹⁸

Individual religiosity. The TeO survey includes several questions which relate to individual religiosity. Our preferred measure is the frequency of attendance of religious ceremonies, a standard measure of religiosity which focuses on religious practice (Iyer 2016). To analyze incentives for veiling we combine this measure with other questions related to individual religiosity: the self-reported importance of religion in the respondent’s life, whether she uses her religion to self-identify, the respect of religious dietary restrictions, and religious marriage. In order to aggregate the answers to these questions into a single measure of individual religiosity, we use a measurement system, as in Heckman et al. (2013) or Bolt et al. (2021), to construct a latent index of individual religiosity. The advantage of this method is that we are able to leverage the variation on several survey questions while keeping the convenience of a single, continuous measure of religiosity. In Appendix A.1 we provide details on the procedure and on the survey questions.

Religious environment. As discussed in Section 2, religious signalling plays a role in women’s decisions to integrate socio-economically and to veil. Drawing on insights from the literature on cultural transmission (Bisin and Verdier 2000), our measures of the influence of other Muslims aim to disentangle vertical transmission (from parents to children) from horizontal transmission (between peers).

To capture vertical religious transmission by parents, our preferred measure is a question on the self-reported importance of religion in the respondent’s education. We also use whether or

¹⁸A limitation of this data is that appreciations like “sometimes” or “always” remain subjective. For instance, a woman who removes her veil in the workplace by obligation might still consider that she “always” wears it – when she is able to. In our data, a few Muslim women do report veiling “always” even though they work in the public sector, where conspicuous religious symbols are prohibited (cf. Section 2).

not the respondent has a religious first name.¹⁹ These measures are then combined into a single index.

To gauge the importance of the religious signal to the local community, our preferred measure is the share of Maghrebi immigrants in the neighborhood.²⁰ We also use a second measure, the local worship capacity per thousand inhabitants. This variable is constructed from our novel data on Muslim worship facilities in France. Since these measures are already continuous, we do not aggregate them.

3.3 Descriptive evidence

Using the TeO data, we describe novel summary statistics on Muslim women in France. We document, in turn, their geographical distribution across France, descriptive statistics by veiling status, and the magnitude of the correlation between veiling and economic participation.

3.3.1 Geographical coverage

The representativeness of the ethnographic studies discussed in Section 2 is limited due to their predominant focus on the Parisian suburbs, some of which are distressed areas that may not accurately reflect the living situations of Muslim women as a whole. In contrast, the TeO survey includes Muslim women from a diverse range of locations, as illustrated in Figure 1. Although some respondents remain concentrated in major urban centers such as Paris, Marseille, and Lille, the survey has a wide geographical coverage across the country.

Table 1: Selected summary statistics by veiling status, Muslim women

		By veiling behavior		
	All Muslims	No symbol	Discreet	Conspicuous
Panel A: demographics and economic outcomes				
<i>Demographics</i>				
Age in 2008	34.59	35.55	26.44	35.99
First-gen. immigrant	0.62	0.61	0.44	0.76
Second-gen. immigrant	0.38	0.39	0.56	0.24
Number of children	1.87	1.78	0.83	2.68
Has a partner	0.61	0.59	0.48	0.73
Not a French speaker	0.10	0.06	0.02	0.25
<i>Labour-force status in 2008</i>				
Employed	0.46	0.54	0.39	0.27

Note: This table reports means of variables of interest by veiling status as defined by the type of symbol. Categories “not important at all” are omitted for religious characteristics to ease interpretation.

Figure 1: Geographical distribution of Muslim women in the TeO survey. Note: Number of places of residence of Muslim women in the TeO survey per *département*. Some *départements* are collapsed together when counts are low due to confidentiality reasons. The top-right subfigure zooms in on Paris and its suburban area.

3.3.2 Summary statistics

Table 1 presents summary statistics for our main variables of interest, disaggregated by veiling behavior. Panel A examines demographic characteristics and economic outcomes, such as employment and educational attainment. The data reveals that veiled Muslim women have significantly worse economic outcomes compared to those who wear no symbol or discreet ones. On average, they are much less educated, less likely to be employed, and have fewer years of work experience, despite being older. Particularly striking is the sharp difference in activity rates (activity being defined as either working, looking for a job, or studying). Almost two-thirds of women who always veil are inactive, compared to less than 20% for non-veiled women, indicating significant barriers to integration linked to veiling.

¹⁹Name-giving has been recognized as an important cultural transmission channel (Fryer and Levitt 2004, Abramitzky et al. 2020, Algan et al. 2022). We classify as religious the names of the Islamic prophet’s wives, Khadija, Sawda, Aicha, Hafsa, Zainab, Hind, Juwairiya, Safiya, Ramla, and Maimuna (Morsy 1989); and of his daughter Fatima. Variations in spelling are permitted. For male first names, we follow Sakalli (2019) by considering a name as religious if it is a variation of the prophet’s name (Mohamed in French) or if it begins with “Abd-” (“servant of...” in Arabic).

²⁰The precise geographical unit is the IRIS level. Having a parent (especially a father) born in Maghreb is a strong predictor of Muslim affiliation in France (Abdelgadir and Fouka 2020).

Panel B examines our primary measures of religiosity and of the respondents’ religious environment. We observe a positive link between veiling and both individual religiosity and that of the environment. On average, veiled Muslim women attend religious ceremonies more frequently, received an education which stressed the importance of religion more, and they live in neighborhoods with higher proportions of Maghrebi immigrants. Our other measures of religiosity and of the respondent’s religious environment confirm these patterns (Appendix Table [A.1](#)).

Discreet symbols. In the TeO survey, we observe the wearing of discreet symbols of religious affiliation. These have received little attention in the literature due to the paucity of data. The French survey reveals that they are worn by Muslim women who are younger, educated, economically active, and moderately religious. In his study of the new veiling movement in Muslim-majority countries, [Carvalho \(2013\)](#) writes that “the movement appears to have originated among *urban, educated, working, middle-class* women” (p. 338). The descriptive patterns in TeO thus suggest that discreet symbols, in the French context, play a similar role to that of the veil in Muslim-majority countries. These symbols are not subject to the multiple prohibitions in public spaces described in Section [2](#). Therefore, they may serve as a tool to reduce the religious costs of integration without imposing an economic cost on Muslim women.

3.3.3 Regression analysis

Our summary statistics suggest a *negative* relationship between economic participation and veiling, but a *positive* one between economic participation and wearing a discreet symbol. We now investigate this further in a regression analysis. We perform two exercises, which complement each other.

First, we explore the relationship between Muslim women’s active status and veiling in the cross-section. With this approach, we are able to include a rich set of controls by using the wide range of information on respondents available in the TeO survey. We also check the robustness

of our results by restricting attention to particular subsamples and by conducting placebo tests on populations other than Muslim women.

Our second approach is to explore this relationship in a panel dataset that we construct from respondents' retrospective accounts of their studies and professional trajectories. Since this retrospective account focuses on a few questions only, our set of controls is more restricted. However, the panel dimension does allow us to verify that the relationship between veiling and economic activity is not merely due to the particular timing of the survey. Timing might indeed be a concern since the survey was conducted around the time of the Great Recession, which may have affected veiled women disproportionately, e.g. if they faced stronger discrimination. Together, the two exercises thus provide a robust assessment of the correlation between veiling and economic participation.

Cross-sectional analysis. Table 2 shows the results of linear regressions where the outcome variable is the activity status (0 if inactive, 1 if active), and the main explanatory variable is the respondent's veiling behavior. Other important explanatory variables include our measures of individual religiosity and the individual's religious environment, economic characteristics which are usual predictors of labor market participation such as education and experience, and other demographic predictors. The sample is restricted to Muslim women with non-missing covariates, yielding 2,433 observations.

Column (1) includes only veiling behavior as regressor. Veiling behavior alone is an important predictor, explaining 14.9% of the variation in the activity status. This regression confirms the pattern observed in the descriptive analysis: while always veiling is negatively correlated with economic integration, (always) wearing discreet symbols is positively associated with the activity rate.

In columns (2) to (6) we add more controls, including dummy variables for birth year, age of arrival in France, birthplace, and region of residence. We further include a set of dummy

Note: This table reports results of linear regressions on a dichotomous variable taking the value of 1 if a woman reports being in the labor force or studying. The other demographic controls are dummies indicating whether the individual is a first-generation immigrant, has an Arabic-sounding first name, has a partner working, has a parent born in France, as well as levels of feelings of French identity. Also included in each regression is a set of dummies capturing the conditions in which the survey took place (whether the partner was present, whether parents were present, survey month dummies, dummies for the interviewer's age group, and interviewer's gender). The religious controls include measures of individual religiosity (levels of importance of religion in own life and of religious practice as well as a dummy indicating whether the woman uses religion to self-identify) and of religious influences from the community (dummies for whether each parent is Muslim, has a religious first name, has a Muslim partner, most of her friends are Muslims, shares of Muslims in the neighborhood, and for levels of importance of religion in her education as well as the number of seats in places of worship in the local area of residence.) The last regression also includes a dummy for whether the individual has right-wing political opinions while the last two regressions also include a quadratic term in work experience and a dummy for completion of a high-school degree. The sample is restricted to Muslim women with no missing covariates. Observations are weighted using the weights provided in the TeO survey. Robust standard errors in parentheses. Level of statistical significance: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$

variables capturing the conditions in which the survey took place (whether the partner was present, whether parents were present, survey month dummies, age group of surveyor dummies, and surveyor’s gender), which gives us confidence that social desirability bias is minimized in our regressions. We include additional groups of control variables one by one to investigate the relative contribution of different mechanisms. The last column reports the results of a regression controlling for all of the covariates. In this last specification, the magnitude of the main coefficients of interest is reduced compared to models with a sparser set of controls. This is expected as veiled women differ on many observable characteristics (see Table 1). Nevertheless, the correlations obtained in the first column remain statistically and economically significant.

The point estimates indicate that Muslim women who always wear a conspicuous symbol are 21.6 p.p. less likely to be active compared to those who never wear any symbol. On the contrary, Muslim women who always wear a *discreet* symbol are approximately 7 p.p. *more* likely to be active. Even in the most parsimonious specification, the effect of veiling is substantial: it is equivalent to having an additional 1.2 preschool-age children. We note, however, that the positive coefficients on discreet-symbol wearing vary more across regressions due to the small size of the subsample. Point estimates associated with wearing a symbol “sometimes” are small and insignificant for both types in the regressions controlling for human capital variables. While this might simply reflect imprecision due to small samples, it may also reflect that not veiling at work does not impose an economic penalty and has a low religious signalling benefit.

3.3.4 Robustness checks.

Overall, the regression results of Table 2 confirm a strong negative association between veiling and economic participation. We further verify the validity of this statement through a series of robustness checks, the results of which are summarized in Table 3. The first three columns correspond to re-estimations of our preferred specification (column 6, Table 2) in different subsamples. The goal of this exercise is to verify that our results are not driven by particular

Table 3: Robustness checks, cross-sectional data

				Other religious groups (placebo)

R^2	0.542	0.399	0.535	0.280	0.628	0.501

Controls included in the regressions are the full set of variables included in Table 2, column (6). In column (1), we exclude students so that the dependent variable becomes labor-market participation. In column (2), the estimation sample is restricted to second-generation immigrant Muslim women (born in France of foreign parents). In column (3), individuals reporting to wear a religious symbol that is neither jewelry, a headcovering, or clothing (symbols labelled as “other”) are excluded from the sample. Columns (4) to (6) estimate the same regression on other religious groups. Robust standard errors in parentheses. Level of statistical significance: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

observations or simply capturing something else apart from the potential impact of veiling. The first column excludes students to use a more conventional measure of economic participation, that is, labor-market participation. The second column excludes individuals born outside France, since summary statistics suggested an important difference in immigration status between veiled and non-veiled women. The third column excludes women whose religious symbol is categorized as Other (i.e. neither Clothing, Headcoverings, or Jewelry) so as to check whether the results for discreet-symbol wearing depend on our categorization. Reassuringly, the point estimate is very similar despite being less precisely estimated.

Columns four to six of Table 3 re-estimate the same specification, this time on groups other than Muslim women, thus providing a form of placebo test. We find that wearing a religious symbol has no significant association with economic participation for Muslim men, nor for women and men with different religious affiliations. These results confirm the unique place of the Islamic veil among other religious symbols, as evidenced by the debates mentioned in Section

2. Whether it is because of individual preferences, signalling motives, legal restrictions on veiling at work, or discrimination, veiling seems to be the only widespread religious symbol which is strongly associated with decreased economic participation.

We further verify that our results are not sensitive to the modelling choice. In Appendix Table A.5, we show that the results are similar when using a logit or probit specification instead of the linear regression model.

Panel analysis. We perform another robustness check in order to control for timing effects, in particular in the event that veiled women’s employment prospects were differentially affected by the 2008 economic crisis (which coincided with the time of the survey). To investigate this possibility, we use the retrospective panel dataset, where we exclude observations for which individuals report multiple activities as well as periods in which the respondent was out of metropolitan France. This empirical strategy allows us to control for time-varying observables and time fixed effects, to substantially increase the number of observations, as well as to include random effects. For the sake of space, we present this analysis in Appendix A.3. The results overall confirm the findings obtained in the cross-sectional analysis, with the wearing of a conspicuous symbol being associated with a significantly reduced economic participation that is similar in magnitude.

Selection on unobservables. Despite using an unusually large set of controls in our regressions, unobserved factors could still drive the correlation between veiling and economic participation. For example, on the marriage market, religious men might prefer veiled and inactive women, and we would thus overstate the extent to which veiling decisions impact economic participation. To assess the extent of selection on unobservables, we use the method proposed by Oster (2019) to compute bias-adjusted lower bounds of our main coefficient of interest.²¹ Results of multiple tests using this approach are reported in Appendix Table A.6. We

²¹Let β be the true impact of always wearing a conspicuous symbol on the activity rate. Oster (2019) shows that a consistent estimator for β is $\beta^* = \hat{\beta}_F - \delta(\hat{\beta}_R - \hat{\beta}_F) \times (R_{max}^2 - \hat{R}_F^2)/(\hat{R}_F^2 - \hat{R}_R^2)$. $\hat{\beta}_F$ and \hat{R}_F^2 are respectively

find that the lower bounds on the coefficient on always wearing a conspicuous symbol remains negative throughout. The magnitude does shrink as we increase the extent of selection on unobservables, but the estimated correlation remains sizeable in the vast majority of our tests.

Veiling and integration in Turkey. Last, the negative correlation between veiling and integration can be observed in another interesting context, namely Turkey. In Appendix B, we use data from Livny (2020) on Turkish districts to examine the relationship between economic participation and veiling. While it is a Muslim-majority country, Turkey also regulated veiling for civil servants, requiring women to uncover their head while on duty, until 2017. We find that women in Turkish districts with higher veiling rates are less integrated economically. This association holds for four measures of economic participation (female primary and secondary school completion, the female literacy rate, and GDP per capita). We take this evidence as an additional illustration that labor-market conditions such as veil bans – and not only the religious environment – do matter for the relationship between veiling and economic participation. This intuition serves as a basis for our conceptual framework, which we now develop.

4 A model of veiling and labor supply

In the previous section, we have shown that veiling displays a strong negative association with economic participation in France. Our discussion of the literature on veiling from Section 2 suggests that such an association can originate from two sources of incentives, namely religious (women who veil are more religious and therefore less likely to engage with an environment they perceive as dangerous) and economic (women who veil face discrimination on the labor market).

In order to structure our empirical analysis of these motives, in this section we model Muslim

our coefficient and the R-squared in a regression including our full set of controls (here, column 6 of Table 2); $\hat{\beta}_R$ and \hat{R}_R^2 are respectively the coefficient and the R-squared obtained from a regression with a restricted set of controls; R_{max}^2 is the R-squared from a regression that includes all observable and unobservable controls; δ is the extent of selection on unobservables relatively to the explanatory power of observables ($\delta = 1$ means equal selection). We test for different values of R_{max}^2 and two values of δ (including the one implying an R^2 of 1) using each of our 5 regressions with fewer controls from Table 2 in Appendix Table A.6.

women’s joint decision of economic participation and veiling. This model builds on the theory of [Carvalho \(2013\)](#), who considered the veil as a tool available for women to mitigate the socio-religious cost of their integration. We then expand on this model by adding economic motives relevant to the Muslim-minority context, namely, those stemming from anti-veil discrimination on the labor market.

Section [4.1](#) briefly describes the basic features of the model. Then, to make clear the intuitions behind the two mechanisms, religious and economic, we present them separately in sections [4.2](#) and [4.3](#).

4.1 Decisions and utilities

We consider a static model in which an agent must simultaneously decide on her labor supply and her veiling behavior. Two activities j are available to the agent: working, denoted $j = 1$, and leisure, denoted $j = 0$. Her labor supply decision thus consists in allocating her total time budget $T = 1$ between time worked, $t_1 = t$, and time devoted to leisure, $t_0 = 1 - t$. Her veiling decision consists in choosing what degree of veiling to adopt at work, v_1 , and what degree of veiling to adopt during her leisure time, v_0 . We assume that the variables v_j can take continuous values between 0 (not veiling) and 1 (wearing a very stringent garment such as the *burqa*, for instance).

The central feature of the model is that the agent’s veiling behavior in activity j affects the flow utility $u_j(v_j)$ that she receives in that activity. Thus, it is the specification of these utilities $u_j(v_j)$ as functions of v_j which will capture the agents’ incentives to veil, from the religious stigma faced by working Muslim women to identity-based discriminations at and outside work.

The complete utility function of the agent, $U(t, v_1, v_0)$, is then obtained by summing these flow utilities $u_j(v_j)$ according to how she decides to spend her time in each activity, to which

we add a disutility of working $d(t)$:

$$U(t, v_1, v_0) = t u_1(v_1) + (1 - t) u_0(v_0) - d(t). \quad (1)$$

Finally, we make some standard assumptions on this disutility of working $d(t)$ in order to ensure existence and uniqueness of solutions to the optimal decision problem, namely that it is increasing and convex, with $d'(0) = 0$ and $\lim_{t \rightarrow 1} d'(t) = \infty$.

It is worth noting that the agent's decision problem is a sequential one: she will first choose the degree of veiling v_j^* which maximizes $u_j(v_j)$ for each activity j , and then choose her labor supply conditional on v_1^* and v_0^* . This sequential decision is possible because the agent is able to situationally adapt her degree of veiling, which we believe is a realistic assumption.

The rest of this section is dedicated to considering the different motives for veiling discussed in Section 2, capturing them using well-chosen utility functions $u_j(v_j)$, and understanding how agents react to these different incentives.

4.2 Religious motives: the Carvalho model

The theoretical mechanism studied by [Carvalho \(2013\)](#) relates to social norms and expectations. In some communities, women may face social pressure to limit their labor supply in order to conform to gender role expectations and maintain social approval. This social pressure can be amplified for religious women who may themselves feel reluctant to integrate into a work environment they perceive as religiously unsafe. Here, veiling can serve a dual purpose for women: first, as a self-commitment to religious beliefs, and second, as a signal to their community of their religious intentions. As a result, veiling can help mitigate the social cost of women's employment, making it a useful tool for their economic integration.

The Carvalho model captures this dual purpose of veiling. In the model, the incentive to veil stems from a combination of the individual religiosity of the agent, r , and of the individual's

religious environment, R . Together, these religious factors determine the penalty that the agent suffers if she engages in religiously-prohibited behavior. This penalty, equal to $-(r + R)$, is both self- and socially-imposed, reflecting personal regret on the one hand, and social stigma on the other hand. It is steeper if the agent herself has higher religiosity, and if her community is more religious. Note also that in this context, both r and R are allowed to be negative, meaning individual or social approval for religiously-prohibited behavior.

Each activity j , working or leisure,²² is then characterized by an exogenous risk of engaging in religiously-prohibited behavior, p_j . Crucially, the agent is able to attenuate that risk by veiling (footnote 9 contains interview excerpts which support this assumption): if she chooses a degree of veiling v_j , then the probability that she engages in religiously-prohibited behavior becomes $p_j(1 - v_j)$. Veiling also entails a cost $c(v_j)$, which Carvalho (2013) interprets for instance as physical discomfort, and we assume that the cost function $c(\cdot)$ is convex, with $c'(0) = 0$ and $\lim_{v \rightarrow 1} c'(v) = \infty$. Finally, there is a material reward m_j associated with each activity j . As a result, the expected utility that the agent derives from activity j is

$$u_j(v_j) = -p_j(1 - v_j)(r + R) - c(v_j) + m_j. \quad (2)$$

Optimal decisions. In the Carvalho model, the exogenous risk of engaging in religiously-prohibited behavior is assumed to be greater at work than during leisure time: $p_1 > p_0$. This assumption implies that a woman will always choose a higher degree of veiling at work than during leisure time, because her marginal utility of veiling will be higher at work.

Regarding the choice of activity, Carvalho considers a discrete choice $j \in \{0, 1\}$ rather than our continuous labor supply decision $t \in [0, 1]$. (The former can be seen as a particular case of the latter, obtained by ignoring the disutility of working, i.e. taking $d(t) = 0$.) The intuition remains however the same in both cases: from the definition (1) of $U(t, v_1, v_0)$, it is easy to see that the agent will work if and only if her indirect utility from working, $u_1^* = u_1(v_1^*)$, is greater

²²Carvalho gives a broader interpretation of this decision as a choice between *integration* or *segregation*.

than that from leisure, $u_0^* = u_0(v_0^*)$. In turn, this happens if and only if the material reward for working m_1 is large enough compared to m_0 ; specifically, if

$$m_1 - m_0 > [p_1(1 - v_1^*) - p_0(1 - v_0^*)](r + R) + c(v_1^*) - c(v_0^*). \quad (3)$$

We summarize these insights in the following proposition.

Proposition 1. In the religious motives model, the agent:

- (i) veils more when she has higher individual religiosity or her community is more religious,
- (ii) always veils more at work than during leisure time,
- (iii) chooses a non-zero labor supply only if the material gains associated to working are sufficiently high.

Carvalho also shows an interesting result, namely that within a range of values of this material reward m_1 , (i) low-religiosity women choose to work, (ii) high-religiosity women choose not to work, and (iii) low-religiosity women veil more than high-religiosity ones. This happens provided that the surrounding population approves of the veil, i.e. $R > 0$. Indeed, in this case low-religiosity working women choose to attenuate the social penalty associated with working by veiling. [Shofia \(2020\)](#) finds evidence for this pattern of veiling among women in Indonesia.

4.3 Economic motives: labor market discrimination against veiling

We now consider a mechanism which relates to the role of discrimination. Veiled women may face discrimination in the workplace due to negative stereotypes or biases held by their employers or colleagues. This discrimination may limit their opportunities for employment or career advancement, and could ultimately lead them to reduce their labor supply. We predict that women with higher earning potential, who face a greater opportunity cost of unemployment or limited career advancement, will incur higher costs associated with veiling.

This veiling-based discrimination on the labor market can also be captured by the utility functions $u_j(v_j)$. To see how, consider a standard consumption–leisure trade-off: the agent has quasilinear utility $\tilde{U}(x, t) = x + g(1 - t)$ where x is her consumption of a numeraire good, $1 - t$ is her leisure time, and $g(\cdot)$ is a concave increasing function. Consumption is the only source of spending, so that the budget constraint is $x = w t$, where w is the agent’s wage rate.

Assume now that discrimination against veiling has a direct negative effect on the agent’s wage, such that an agent with earning potential w who also chooses a veiling level v_1 at work gets the effective wage $w(1 - v_1)$. This assumption broadly reflects that since discrimination typically makes it more difficult for women who wear the veil to secure and keep a job or to advance in their career (cf. Section 2), the associated cost of veiling should be greater for women with higher earning potential. For instance, we could expect the opportunity cost of job loss or slower career progression to be proportional to one’s earning potential. With this assumption, the budget constraint of the agent becomes $x = w(1 - v_1)t$.

Aside from the cost associated to discriminations, suppose that veiling at work provides some marginal return y to the agent (maybe through the religious incentive mechanism discussed above), and entails an intrinsic cost $c(v_1)$. In this case, her utility function is

$$U(t, v_1) = [w + (y - w)v_1 - c(v_1)] t + g(1 - t). \quad (4)$$

This utility can be seen as a particular case of equation (1), obtained by taking $u_1(v_1) = w + (y - w)v_1 - c(v_1)$, $u_0(v_0) = -c(v_0)$ (so that $v_0^* = 0$), and $d(t) = -g(1 - t)$ (so that $d(\cdot)$ is increasing and convex, consistent with our earlier assumption).

Note that in this model, discriminations against veiled women are essentially interpreted as inherent preferences on the employer side (i.e. taste-based discrimination). A more refined model could consider instead that these discriminations arise out of rational expectations formed by the employer about the religiosity of the veiled woman. Indeed, as discussed in Section 2,

employers often justify their preferences against veiled women by invoking conflicts at work around religion, or lower productivity induced by religious practice. Many other factors could rationalize this kind of statistical discrimination: for instance, religious women could be seen as a risky human capital investment for employers if they tend to stop working after they get married or have children. Furthermore, women are forbidden to wear the veil in most public sector professions, effectively reducing their employment opportunities. [Adida et al. \(2016\)](#), using a series of experiments and ethnographic work with Senegalese immigrants in France, find evidence of *both* statistical and taste-based discrimination. However, our data do not contain information on the employer side which could allow us to distinguish between these two sources of discrimination. Therefore, we choose not to model the labor-demand side, and rather analyze labor-market choices from the point of view of Muslim women.

Optimal decisions. While the Carvalho model made predictions linking veiling behavior and labor supply to religiosity (individual and social), the model (4) instead makes predictions linking these outcomes to her earning potential. Specifically, since women with a higher earning potential incur a higher marginal disutility of veiling, there must be a negative correlation between the earning potential w and the degree of veiling at work v_1 . Furthermore, with a marginal utility $(1 - v_1)$ for w , women with higher wage potential should work more than those with a lower wage. Both of these results are a direct consequence of veiling having a negative, proportional impact on the agent's effective wage.

We summarize this intuition with the following proposition.

Proposition 2. In the economic motives model, the agent:

- (i) veils less when she has a higher earning potential,
- (ii) spends more time working when she has a higher earning potential.

Of course, these results do not contradict those from proposition 1 directly, since the two models consider different mechanisms. Yet, the two mechanisms above mostly play in opposite

directions. According to the first mechanism, women who are religious or who have more religious incentives to signal piety to their community have an incentive to veil at work in order to mitigate the social penalty associated with working. But according to the second mechanism, discrimination at work provides an opposite incentive to unveil at the workplace.

It is worth noting that in the French context, the disproportionate economic discrimination against women wearing conspicuous religious symbols, in the form of policies banning the veil in certain professions, might lead to specific integration strategies involving discreet religious symbols. Indeed, as we discussed in Section 3.3, discreet symbols are mostly adopted by young, moderately religious, educated Muslim women. In appendix C we extend our model to show how it can rationalize this empirical pattern related to discreet religious symbols, by assuming that wearing conspicuous symbols entails a disproportionate economic cost.

In the next section we pool the religious and economic motives together in a unified empirical model, and we derive new testable predictions from the interaction of the two mechanisms described above. We then use data on veiling behaviors and employment of Muslim women to quantify the various effects at hand.

5 Empirical analysis

5.1 Econometric model

Our econometric specification is derived by pooling together the two motives for (un)veiling described in the previous section, religious and economic. To capture these motives, we focus on three main individual characteristics: individual religiosity r_i , the individual's religious environment R_i , and earning potential w_i . We obtain a unified expression for the utility that

woman i receives in activity j by choosing the degree of veiling v :²³

$$u_{ij}(v) = \underbrace{-p_j(1-v)(r_i + R_i)}_{\text{religious motives}} + \underbrace{\mathbf{1}_{\{j=1\}}w_i(1-v)}_{\text{economic motives}} - c(v). \quad (5)$$

Our empirical approach relies on measures of the individual characteristics r_i , R_i , and w_i . We use the data and constructed measures that we described in Section 3.2. Regarding individual religiosity, we use our index measure aggregated from six different survey questions, Religiosity_i . Regarding the signalling motive, we use our index measure of vertical religious influence, $\text{VertiReligiousInf}_i$, and two measures of the religiosity of the woman's environment, ShareMaghrebi_i (the share of Maghrebi immigrants in the individual's neighborhood) and MosqueCapacity_i (the local capacity for Muslim worship). Regarding the earnings potential, we use measures of human capital, namely years of schooling, Education_i , and years of work experience, Experience_i . To summarize, we use the following proxies for the individual characteristics of woman i :

$$r_i \sim \text{Religiosity}_i \quad (6)$$

$$R_i \sim \text{VertiReligiousInf}_i + \text{ShareMaghrebi}_i + \text{MosqueCapacity}_i \quad (7)$$

$$w_i \sim \text{Education}_i + \text{Experience}_i. \quad (8)$$

Next, we formulate an econometric model informed by the theory which is based on these variables. We use a multinomial logit model to explain the joint decision of activity and veiling, (j, v) , with two activity statuses $j \in \{0 = \text{Inactive}, 1 = \text{Active}\}$ and three levels of veiling $v \in \{0 = \text{None}, 1 = \text{Intermediate}, 2 = \text{Always conspicuous}\}$. Due to the low sample sizes in the three intermediate veiling categories, we group discreet-symbol wearing and sometimes wearing a conspicuous symbol into an Intermediate category. Adapting equation (5) into an econometric

²³We let the material payoffs m_j in equation (2) to be also individual-specific by taking them equal to $\mathbf{1}_{\{j=1\}}w_i(1-v)$, thus combining the religious and economic motives described in Section 4.

Table 4: Correspondence between estimated parameters and theoretical model

Explanatory variable	Parameter	Proportional to...	Varies with v	Varies with j
<i>Religiosity variables</i>				
Religiosity _{i}	β_{jv}^1	$-p_j(1-v)$	+	−
VertiReligiousInf _{i}	β_{jv}^2	$-p_j(1-v)$	+	−
ShareMaghrebi _{i}	β_{jv}^3	$-p_j(1-v)$	+	−
MosqueCapacity _{i}	β_{jv}^4	$-p_j(1-v)$	+	−
<i>Economic variables</i>				
Education _{i}	γ_{jv}^1	$\mathbf{1}_{\{j=1\}}(1-v)$	−	+
Experience _{i}	γ_{jv}^2	$\mathbf{1}_{\{j=1\}}(1-v)$	−	+

discrete-choice model which uses the proxies described above,²⁴ the utility for woman i to jointly choose activity j and veiling level v is given by

$$\begin{aligned}
u_{ijv} = & \alpha_{jv} + \beta_{jv}^1 \times \text{Religiosity}_i + \beta_{jv}^2 \times \text{VertiReligiousPressure}_i \\
& + \beta_{jv}^3 \times \text{ShareMaghrebi}_i + \beta_{jv}^4 \times \text{MosqueCapacity}_i \\
& + \gamma_{jv}^1 \times \text{Education}_i + \gamma_{jv}^2 \times \text{Experience}_i + X_i' \theta_{jv} + \varepsilon_{ijv}. \quad (9)
\end{aligned}$$

Here X_i is a set of individual-level controls, and ε_{ijv} is the unobserved part of the utility. The coefficients β_{jv} , γ_{jv} and θ_{jv} are estimated with respect to the baseline $(j, v) = (0, 0)$ (i.e. being inactive and not veiling). We assume that the unobserved components of utility ε_{ijv} are distributed i.i.d. Gumbel, giving rise to a standard multinomial logit model in which the probability for i to choose alternative (j, v) is

$$\frac{\exp u_{ijv}}{\sum_{(j', v')} \exp u_{ij'v'}}. \quad (10)$$

5.2 Implications of the model

The religious and economic motives channels from the model have separate but clear implications regarding how the estimated parameters should vary with j and v . Table 4 outlines the

²⁴As mentioned above, moving from continuous to discrete choice is simply achieved by taking $d(t) = 0$.

correspondence between the parameters of our estimating equation (9) and the theoretical components of the model. To interpret the associated implications, we categorize our explanatory variables into two groups: “religiosity variables,” which are associated with the religious motives behind the joint decision of economic participation and veiling and are linked to the β_{jv} parameters (β_{jv}^1 , β_{jv}^2 , β_{jv}^3 , and β_{jv}^4); and “economic variables,” which are associated with economic motives and are linked to the γ_{jv} parameters (γ_{jv}^1 and γ_{jv}^2).

We describe below the empirical implications of the religious and economic motives of the model for our parameter estimates. Since the same implications apply to β_{jv}^1 , β_{jv}^2 , β_{jv}^3 , and β_{jv}^4 on the one hand, and to γ_{jv}^1 and γ_{jv}^2 on the other hand, we drop the superscripts and make statements about the generic parameters β_{jv} and γ_{jv} instead.

Implication 1. Within activity,

(a) religiosity variables have a milder (negative) impact on utility for women who veil more:

$$\text{at } j \text{ fixed, } \beta_{j0} < \beta_{j1} < \beta_{j2},$$

(b) economic variables have a milder (positive) impact on utility for women who veil more:

$$\text{at } j \text{ fixed, } \gamma_{j0} > \gamma_{j1} > \gamma_{j2}.$$

Implication 2. For a given degree of veiling,

(a) religiosity variables have a stronger (negative) impact on utility for women who participate economically:

$$\text{at } v \text{ fixed, } \beta_{0v} > \beta_{1v},$$

(b) economic variables have a stronger (positive) impact on utility for women who participate economically:

$$\text{at } v \text{ fixed, } \gamma_{0v} < \gamma_{1v}.$$

To interpret these implications of the model, let us focus on the meaning of the parameters to

estimate. For instance, the parameter β_{jv}^1 indicates how own religiosity impacts the probability of choosing the alternative (j, v) . According to the theory, this impact is negative since religiosity implies more limitations on acceptable behavior and a higher intensity of regret. In magnitude, the impact should be milder for women who veil – this is the purpose of veiling in the Carvalho model – hence β_{jv}^1 should be increasing in v (Implication 1a). Furthermore, the impact should be greater for working women – because the work environment is more risky than the home environment – hence β_{jv}^1 should be decreasing in j (Implication 2a). Similar predictions apply for β_{jv}^2 , β_{jv}^3 and β_{jv}^4 , which relate to the individual’s religious environment.

Next, the parameter γ_{jv}^1 indicates how education impacts the probability of choosing the alternative (j, v) . In the model education plays a role by increasing the working wage. Therefore the impact of education should be lower for women who veil more – they have lower expected wage because of discrimination (Implication 1b); and it should be greater for women who work compared to those who do not (Implication 2b). Similar predictions apply to γ_{jv}^2 , which relates to professional experience.

Implications 1 and 2 above focus on veiling and economic participation choices independently. However, our main interest is to understand how veiling and economic participation choices interact, and in particular whether religious and economic motives are relevant mechanisms in this interaction. These mechanisms will be captured by studying the signs of double differences in the parameters β_{jv} and γ_{jv} .

First, according to the religious motives mechanism, the religious benefits of veiling are greater for women who integrate economically. This is stated formally as follows:

Implication 3: Religious motives channel. The religious returns on utility to increasing one’s degree of veiling are larger for women who participate economically, compared to those who don’t:

$$\text{for } v < v' \text{ fixed, } \beta_{1v'} - \beta_{1v} > \beta_{0v'} - \beta_{0v}.$$

Second, according to the economic discrimination mechanism, the economic losses induced by veiling are greater for women who integrate economically. This is stated formally as follows:

Implication 4: Economic discrimination channel. The economic returns to being economically active are smaller for women who veil, compared to those who don't:

$$\text{for } v < v' \text{ fixed, } \gamma_{1v'} - \gamma_{0v'} < \gamma_{1v} - \gamma_{0v}.$$

Having established these empirical implications of the model's different mechanisms, we now turn to the estimation and to testing the model implications 1–4.

5.3 Results

Table 5 presents the results for the estimation of equation (9). Recall that all parameter estimates are relative to the baseline of an inactive woman who never wears religious symbols. This estimation is performed without controls – in Appendix A.5 we perform the same exercise while including controls, and observe that results remain sensibly similar.

The parameter estimates suggest two main findings. To ease interpretation, we focus on the predicted marginal effects (panel B in Table 5). First, individual religiosity is a strong and significant predictor of changes in veiling behavior, but the same observation does not hold for the individual's religious environment. For example, we estimate that a 1 standard deviation increase in individual religiosity decreases the probability of not wearing any religious symbol and being active (resp. inactive) by 19 percentage points (resp. 8 p.p.). On the contrary, it increases the probability of wearing a conspicuous symbol and being active (resp. inactive) by 12 percentage points (resp. 13 p.p.). Signalling motives (both vertical and horizontal) are also associated with higher degrees of veiling, although most parameter estimates are not significantly different from 0 at the conventional levels. For instance, a 1 s.d. increase in vertical religious transmission is associated with an 19 p.p. increase in the probability of wearing a conspicuous

symbol and being inactive, while an extra Muslim worship seat per 100 inhabitants is associated with a 9 p.p. increase in the same probability. Overall, both the magnitude of the estimates and their significance level suggest that individual religious motives are the strongest predictors of veiling behavior, above (and conditional on) the individual's religious environment.

Second, both schooling and work experience substantially increase the probability of being active and decrease the probability of veiling. For instance, an additional year of schooling is associated with a 1.8 p.p. increase (resp. 0.7 p.p.) in the probability of being active and wearing no symbol (resp. wearing a discrete symbol). Interestingly however, these human capital factors are not associated with an increase in the probability of being active while wearing a conspicuous symbol. This result might suggest that veiling at work offsets the benefits of human capital on economic activity, an expected consequence of the labor-market discrimination channel.

We illustrate these results in Figure 2 by plotting the utility obtained by veiling for an

Table 5: Determinants of joint employment and veiling decision, multinomial logit.

Note: This table reports estimates of the parameters of the econometric model (9). The baseline category is the choice of inactivity and not wearing any religious symbol. Individual religiosity and vertical religious pressures are measured as indices (with mean zero and variance 1) constructed from multiple proxies available in the TeO data (see Appendix A.1 for details). ShareMaghrebi _{i} is the proportion of the local population that is of Maghrebi origin. CapacityMosques _{i} is the estimated capacity in Muslim places of worship in the area of residence. Robust standard errors in parentheses. Point estimates in bold are significant at the 1% level ($p < 0.01$), * $p < 0.05$, ⁺ $p < 0.1$.

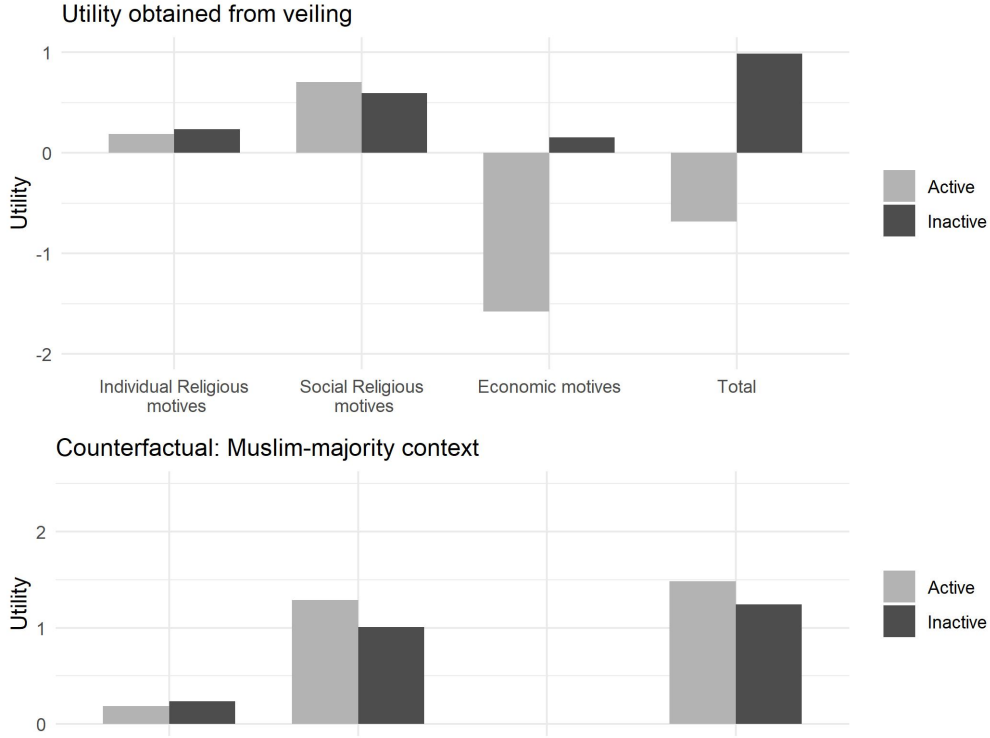

Figure 2: Utility obtained from veiling (i.e. difference of utility between choosing $v = 0$ and $v = 2$) according to the estimates of Table 5, and based on an ‘average’ woman in our sample (cf. footnote 25). The lower panel is obtained by counterfactual, shutting down the economic discrimination channel and modifying some environmental characteristics of this average woman to reflect a Muslim-majority environment (cf. footnote 26).

‘average’ woman in our sample, according to our estimates.²⁵ We observe that this average woman has a disincentive to veil overall if she is active, which is a consequence of the economic motives being stronger than the religious ones. On the contrary, an inactive woman has an incentive to veil, because she is less affected by economic motives.

We then compute the same utilities in a counterfactual, Muslim-majority environment in which there is no economic discrimination against wearing the veil at work.²⁶ In this case, we see that active and inactive women have somewhat equivalent incentives to veil, which sharply contrasts with our findings in the French setting. Active women benefit slightly more from

²⁵ We set the following values for this ‘average’ Muslim woman: Individual Religiosity: 0.1, Vertical Religious Influence: 0.1, Local share of Maghrebi immigrants: 0.4, Muslim worship seats per thousand inhabitants: 2.21, Schooling: 11.16 years, Work experience: 5.85 years. One can compare those values with the summary statistics of Tables A.1 and A.2 to verify that this roughly corresponds to an average Muslim woman in our sample.

²⁶ To compute this counterfactual, we shut down the economic discrimination channel, and set the share of local Maghrebi immigrants to 0.75 (instead of 0.4) and the number of worship seats to 4 (instead of 2.21). Note that we obtain a similar figure if we double the value of the vertical religious influence.

veiling than inactive ones overall, a finding which is consistent with the religious channel of the [Carvalho \(2013\)](#) model and with the evidence from [Shofia \(2020\)](#) on Indonesia, although the difference here is small.

In the rest of this section, we verify these results formally using the tests formulated in Implications 1–4. Detailed results for these tests are available in [Appendix A.4](#).

Baseline implications. Implications 1 and 2 concern the direction of variation for the coefficients β_{jv} and γ_{jv} , respectively with the veiling level v and the activity j . Tests of these implications should indicate whether our joint outcomes react to our predictors in the direction expected by the model.

Implication 1. Our first model implication concerns the relationship of our predictor variables with veiling behavior, within a given economic activity. Consider for instance our measure of individual religiosity. We can see clearly from [Table 5](#) that individual religiosity is associated with an increase in the degree of veiling, both for active and inactive women. Indeed, at activity j fixed, our estimates for β_{jv}^1 increase across veiling levels v , indicating that higher measures of individual religiosity are associated with an increased propensity to wear the veil.

To verify this formally, we conduct hypothesis tests of the form $\beta_{jv'}^1 - \beta_{jv}^1 > 0$ for the different possible combinations of j , v and v' such that $v' > v$. (We present the detailed results in [Figure A.1](#), [Appendix A.4](#).) In this case, we find that Implication 1 holds at the 95% confidence level for nearly all possible combinations of v and v' , thus confirming the positive association between individual religiosity and veiling.

We then perform similar tests of Implication 1 for our five other main predictors. Most of our point estimates for the tests associated with the different predictors agree with Implication 1, although several tests do not reach statistical significance. Regarding vertical religious influence, four estimates out of six fall in the predicted region. For our first measure of horizontal influence,

i.e. the percentage of people from Maghrebi origin in the neighborhood, five out of six point estimates fall in the predicted region. For our second measure of horizontal influence, i.e. the local number of seats in religious facilities per 1000 inhabitants, four out of six point estimates fall in the predicted region, with three of those being significant at the 95% confidence level. Finally, both for our work experience variable and for our schooling variable, four out of six point estimates fall in the predicted region, with three of those being significantly different from zero.

Furthermore, if we ignore the “discreet symbols” veiling category for which we have few observations, then our point estimates systematically fall in the half-space predicted by the model, with a majority of the tests yielding statistically significant predictions.

Put together, we interpret these results as providing partial evidence for Implication 1. Although a majority of the tests do not hold at the 95% level, the overall pattern of point estimates falling in the predicted region suggests some validity for the statement of Implication 1. Notably, statistical power might be an issue here, as we observed by discarding the estimates linked to the ‘discreet symbols’ category, for which we have few observations: doing so decreases the rejection rate for our tests. Overall, the tests of Implication 1 thus confirm that our religiosity variables are broadly associated with an increased propensity to veil, while our economic variables are associated with a decreased propensity to veil.

Implication 2. Our second implication concerns the relationship of our predictor variables with economic activity, holding the degree of veiling fixed. As we did with Implication 1, we perform tests of Implication 2 for our six main predictors, the results of which are presented in Figure A.2. First, regarding our four religiosity variables, there does not seem to be much support for Implication 2. There is no systematic pattern for point estimates as we observed for Implication 1, and all tests fail at the 95% confidence level. Therefore, we do not find any evidence for our religious variables being associated with an increased or decreased propensity

to be economically active.

On the contrary, we find that our economic variables are strongly associated with economic activity. Indeed, Implication 2 holds for both our work experience and schooling variables. This indicates a strong positive association between these economic variables and the propensity to be economically active.

Since we do not find that religiosity variables are strongly associated with the propensity to be economically active, the “religious motives channel” is already undermined by the tests of Implication 2. This is because this channel predicts that, when holding the degree of veiling constant, women who are more religious or who live in communities that are more religious should be less economically active. However, this is not what we find here: our results suggest that the religiosity variables do not have a direct effect on economic participation, but only an indirect one through the practice of veiling. We discuss this further with the test of Implication 3 below.

Mechanisms. We now move on to the tests of Implications 3 and 4, which are more directly related to the two mechanisms that we highlighted above: the religious motives channel, and the economic discrimination channel.

Implication 3. Our third implication can be interpreted as a formal test for the religious motives channel, since it examines whether veiling has higher religious returns for women who are economically active, compared to those who are not. Our results for these tests are presented in Figure A.3. In this case, neither test significance nor point estimates suggest that the formal statement of Implication 3 holds. As such, we do not find evidence for this mechanism.

This result is in line with those of the tests for Implication 2, which already suggested an absence of association between our religious variables and economic participation among Muslim women. Taken together, these results point towards religious motives having an effect on economic participation only through the practice of veiling. This supports the idea that

the negative correlation between veiling and economic participation that we observed in the descriptive analysis may be mostly due to veiling having a cost on the labor market, as opposed to religious women having different preferences from non-religious women regarding economic participation.

Implication 4. Finally, our fourth implication can be interpreted as a formal test for the economic discrimination channel, by examining whether economic participation has higher returns for women who do not veil, compared to those who do. Results are presented in Figure [A.4](#).

Regarding our first economic variable, years of schooling, we do not find support for the statement of Implication 4: the tests reject the hypothesis at the 95% confidence level, and there is no pattern of point estimates mostly belonging to the predicted region. However, we find some support in the tests associated with our second economic variable, work experience, which most women in our sample had time to complete. In this case, all point estimates fall within the predicted region. Furthermore, the test which ignores the “discreet symbols” category suggest statistically significant differences at the 90% level. The absence of a clear pattern for schooling is perhaps because, on average, the differences in schooling levels by veiling status are not as stark as those for work experience (see Table [A.1](#)).

This second result supports the economic discrimination channel: higher-educated women are less likely to integrate economically if they veil, even if we hold religiosity variables constant. In other words, the utility returns on schooling are lower for women who veil compared to those who do not. We have seen in our discussion of Implication 2 that this seems to be unrelated to an underlying preference towards economic participation linked with individual religiosity or religious influence. Therefore, this result seems to support the idea that there is an economic cost to veiling, in the sense that veiled women face weaker economic opportunities than those who do not veil.

To sum up, our results suggest that the interaction between the decision to veil and that of economic participation is mostly driven by economic concerns. First, both religious motives and economic ones play important roles in the decision to veil. Second, while economic motives are strong drivers of economic participation, the same is not true for religious motives, suggesting that the veil itself (and not underlying religious preferences) is linked to decreased economic participation. Third, non-veiled women seem to enjoy higher economic returns on their education compared to veiled women (holding individual religiosity and the religious environment fixed), as evidenced by their higher propensity to be economically active.

Overall, those results suggest that the religious mechanism suggested by [Carvalho \(2013\)](#) cannot fully explain veiling and economic participation patterns in France. Instead, the interaction between veiling and the economic incentives to economic participation, such as the discrimination against veiled women on the labor market, seems to play an important role in this context. Furthermore, and of particular importance for the French debate, we note that individual religious motives turn out to be at least as important as communitarian influences in the decision to veil.

6 Conclusion

Theoretical and empirical studies of veiling in economics have so far mainly focused on Muslim-majority countries, perhaps because of the paucity of data on veiling in Western countries. With the rising immigration flows of Muslims to secular countries, getting a better understanding of why women veil is nonetheless crucial as many countries, of which France is maybe the most emblematic, limit the expression of religious faith in public.

In this paper, we tackle this question using rare rich observational data on Muslim women in France. The richness of the data notably allows us to distinguish between private and communitarian incentives to veil. We first document that in France, wearing conspicuous religious symbols is associated with a much lower economic integration for Muslim women.

The magnitude of this relationship is large, comparable to having a child less than 4 years old for instance. Second, we find that, among the main incentives for veiling highlighted in the economic literature, the wearing of conspicuous symbols appears to be strongly driven by private religious motivations. Third, we find that the joint decision to veil and being economically active can be mostly explained by economic (dis)incentives. Our results thus suggest that the veiling mechanism proposed by [Carvalho \(2013\)](#) and evidenced in the context of Indonesia by [Shofia \(2020\)](#) may be second-order in a non-Muslim-majority country such as France. When choosing whether to work and to wear the veil, Muslim women seem to be more sensitive to incentives related to how veiling impacts their economic opportunities. Instead, we find that the wearing of discreet symbols is more in line with the religious incentives highlighted in these studies.

Because they underline the role of private religious motives instead of signalling ones, our results question the rhetoric often used to justify policies restricting the wearing of religious symbols in France. In the media and in political spheres, journalists and politicians almost always defend veiling restrictions on the basis that Muslim women are being forced to veil by their husband and community. If these claims were true, it is believed that secular policies could have the potential to “free” Muslim women from religious pressures and promote gender equality (e.g. [Maurin and Navarrete-Hernandez 2023](#)). Actually, even in this case, [Carvalho \(2013\)](#) shows that banning the veil in public spaces might lead to *more* segregation because women would lose the ability to signal their piety to their community. However, consistent with existing evidence from qualitative interviews with Muslim women, we find that the main incentives for veiling appear to be private. In other words, Muslim women who veil do so for personal reasons linked to their own beliefs, first and foremost. Therefore, further restricting the wearing of conspicuous religious symbols is likely to lead to even poorer integration of Muslim women if these private benefits are high and discreet symbols are imperfect substitutes. Our complementary analysis of the Turkish case, a country which also imposed secular constraints in the public sphere, is consistent with this argument.

Our empirical approach in this paper is descriptive and should not be interpreted as causal. Still, our findings suggest two key takeaways: (i) women who veil are less economically active primarily due to economic penalties affecting their integration, rather than underlying preferences linked with their religiosity; and (ii) individual religious motives outweigh the social signalling ones in their decision to veil. Given the importance of better integrating Muslim populations in developed countries, future work could provide more robust assessments of these two takeaways. The specific obstacles that veiled women face in the labor market – whether legal restrictions, hiring discrimination as evidenced by [Valfort \(2020\)](#), workplace challenges, or others – require careful examination to assess their respective impact on economic participation. Additionally, larger datasets could help better disentangle individual versus social motives for veiling, for instance by leveraging external shocks to the local religious composition, such as migration waves. We finally note that data limitations inherent to studies like ours call for more initiatives like the TeO survey to better document the experiences of minority populations in a context of increasing global migrations.

A Data and additional results

A.1 Measurement of individual religiosity and signalling motives

The TeO dataset contains rich information on respondents’ religious life. We first describe the variables we use to proxy for individual religiosity, vertical religious influence (from parents), and horizontal pressures (from Muslim peers). We then detail how we combine those multiple measures into meaningful indices through a measurement system.

Individual religiosity. In TeO, we measure individual religiosity using survey questions on the frequency of attendance of religious ceremonies, the self-reported importance of religion in the respondent’s life, whether she uses her religion to self-identify, the respect of religious dietary restrictions, and religious marriage. We list details of these variables below:

Variable name	Values	Question	Type
attendance of religious ceremonies	never; for familial ceremonies only; for religious feasts only; one or twice a month; weekly	“How often do you attend religious ceremonies?”	ordinal
importance of religion in respondent’s life	no importance; a little; quite important; very important	“What importance do you give to religion in your life today?”	ordinal
uses religion to self-identify	yes; no	“Among the following characteristics, which ones define you best? [...] Your religion?”	indicator
respect of dietary restrictions	never; sometimes; always; none (coded as a dummy if “always”)	“In your daily life, do you respect your religion’s dietary restrictions?”	indicator
religious marriage	yes; no	“Did you and your husband do a religious wedding?”	indicator

Vertical religious transmission. We measure vertical religious transmission using two variables, namely the self-reported importance of religion in the respondent’s education and religious name-giving.

Variable name	Values	Question	Type
importance of religion in education	no importance; a little important; quite important; very important	“What importance did religion have in the education you received in your family?”	ordinal
religious first name	yes; no	constructed by authors using respondent’s first name	indicator

Religious environment. We measure the individual’s religious environment using two variables, namely the share of Maghrebi immigrants in the respondent’s neighborhood (IRIS) and the local capacity in Muslim places of worship. In TeO, the share of Maghrebi immigrants is reported in deciles of the distribution across France. We select the middle point of each bin, except for the extremes – zero or above 40%, where we set the value of the variable to 0 and 0.4 respectively. Our second proxy of local Muslim presence is the estimated capacity (by the Muslim association who produced the inventory) in Muslim places of worship at the local level. In TeO, this is measured at the *commune* (municipal) level of residence for all French cities except Paris, Lyon, and Marseille, for which we observe the *arrondissement*.

Measurement system. For the first two concepts above, since there is no natural way to combine the ordinal and indicator variables into meaningful indices, we formulate a measurement system. We are interested in two latent variables, *individual religiosity* and *vertical religious pressure*, which we assume load into their respective proxies listed above. We interpret those proxies as noisy measures of the associated unobserved, underlying concept. Denote by Z and W the vectors of proxies for individual religiosity and for vertical pressure respectively. We assume ordinal relationships between measures $\{Z, W\}$ and underlying factors $\text{IndivReligiosity}_i$ and VertPressure_i :

$$Z_{i,j} = \mu_{1,j}^z + \lambda_j^z \text{IndivReligiosity}_i + \varepsilon_{i,j}^z \quad (11)$$

$$W_{i,j} = \mu_j^w + \lambda_j^w \text{VertPressure}_i + \varepsilon_{i,j}^w \quad (12)$$

where ε are measurement errors assumed to be i.i.d. and to follow a logistic distribution. As the latent factors do not have a natural scale or location, to simplify interpretations, we normalize the means of $\text{IndivReligiosity}_i$ and VertPressure_i to zero, and their variances to one. We then predict the latent factors for each individual by calculating their empirical Bayes means ([Skron dal and Rabe-Hesketh 2009](#)).

A.2 Summary statistics (TeO)

We present some novel summary statistics of Muslim women by veiling status in Table [A.1](#). We distinguish between four categories for the wearing of religious symbols, which depend on (1) whether the symbol is “discreet” or “conspicuous”, and (2) whether it is worn “sometimes” or “always”. Since there is very little variation in the number of symbols worn (most women report

only wearing one), we do not use that information and focus on the extensive margin. Along with the outside option of not wearing any symbol, we thus compare five veiling levels. In terms of the theoretical model, we interpret the veiling level (v) as being increasing in the following order: no symbol ($v = 0$), sometimes worn, and always worn. Overall, Muslim women wearing conspicuous religious symbols differ from other Muslim women in many respects. For example, they are on average older, have more children, and are more likely to live in a couple. Moreover, while most Muslim women wearing a discreet symbol are second-generation immigrants, the vast majority of women who wear a conspicuous symbol are first-generation immigrants. In line with a potential learning of the French social norms by women wearing discreet symbols compared to those wearing the veil, the former are more likely to report being discriminated against for non-religious reasons, not to trust the French institutions, and to believe that racism is widespread in France.

In Table A.1, we report summary statistics of all religion-related variables by veiling status. As expected, as we move toward “higher” veiling status, individuals report higher degrees of religiosity and live in more religious environments. For example, 79% of women who always wear conspicuous symbols report that religion is very important in their life, while less than half of women not wearing a religious symbol do so. Women wearing discreet symbols appear to be moderately religious, but still report higher degrees of religiosity than women without any symbol. Women who wear conspicuous symbols also seem to live in more religious environments: they are more likely to have a Muslim partner and to report that most of their friends are Muslims. Moreover, they live in communes (and neighborhoods) populated by a larger Muslim community (proxied by Maghrebi immigrants and Muslim places of worship). Veiled women also seem to be subject to stronger parental religious pressures. They are significantly more likely to report that religion was very important in their education and to be given a religious first name. In short, all of the core potential mechanisms mentioned so far display some association with veiling behavior in the expected directions (see Table 4).

The main fact that motivates the first part of our analysis is that women wearing religious symbols, in particular those who always do so, have much poorer labor-market and schooling outcomes than the rest of the sample. Indeed, women who always wear conspicuous religious symbols are much less economically active on average. Our measure of economic activity is the activity rate, that is, whether the woman is either working, studying, or looking for a job (unemployed) at the time of the survey. While less than 20% of women not wearing conspicuous

symbols are inactive at the time of the interview, this proportion increases to 30% for women who sometimes wear a conspicuous symbol and up to 64% for women who always do. Moreover, while 20% of women not wearing a symbol report having never worked in their life, almost half of women who always veil indicate having never entered the labor force. In terms of schooling outcomes, Muslim women who wear a conspicuous symbol are less likely to have any schooling degree. They have completed, on average, 2 to 7 fewer years of schooling than Muslim women who wear discreet symbols or none. Overall, the data suggests that wearing the veil seems to be strongly associated with a decline in economic integration, but this correlation may be due to many other factors over which veiled women differ from other Muslim women. We therefore provide a more thorough regression analysis of this pattern in our empirical approach.

A.3 Analysis of panel data

Exploiting the respondents' employment history available in the TeO data, we construct a retrospective panel dataset of economic activity to test the robustness of our results to the timing of the survey. We restrict the sample to adults, meaning that we remove observations for which an individual is aged less than 18 years old. This sample selection is made because it can be plausibly assumed that the veiling decision, on average, is made before adulthood.²⁷ We estimate random effects models using this data and report results in Table A.3. In column (1), we regress the activity rate on veiling status and year fixed effects. In columns (2) and (3), we include, in turn, time-varying observables and time-invariant controls. The time-invariant controls are all covariates and dummies included in the cross-sectional analysis that are not likely to have changed over time (at least after age 18). These include the mother's and father's religion (Muslim or other), whether the individual has an Arabic-sounding name, attendance of religious ceremonies (proxy for religiosity), self-reported feelings of French identity, the importance of religion in the respondent's education, birthplace dummies, and a set of survey fixed effects. In these regressions, we cluster standard errors at the individual level to account for serial correlation. However, we cannot include individual fixed effects because we do not have panel data on veiling. We thus implicitly assume that the veiling decision is permanent, which we argue

²⁷In the case of the Islamic veil, ethnographic evidence shows that the decision is usually made between the age of reaching puberty and around 20 years old (Gaspard and Khosrokhavar 1995). According to Islamic prescriptions, girls are supposed to dress modestly (including covering their hair) when reaching puberty so as to reduce men's temptation. In reality, in France, many adolescents or young women choose to veil a few years after reaching puberty, that is, around adulthood. We also verify that our results are not sensitive to the 18 years old threshold. In a robustness check, we restrict the sample to individuals aged at least 25 years old and find similar results.

Table A.1: Summary statistics by veiling status, Muslim women

Veiling status:	All	No		
	Muslims	symbol	Discreet	Conspicuous
<i>Demographics</i>				
Age in 2008	34.59	35.55	26.44	35.99
First-gen. immigrant	0.62	0.61	0.44	0.76

<i>Presence of Muslim places of worship in commune (or arrond.)</i>				
Places of worship (/1000 inh.)	0.05	0.05	0.04	0.06
Capacity in a place of worship (/1000 inh.)	13.06	10.82	8.11	23.42
Capacity for women in a place of worship (/1000 inh.)	2.21	8.97	6.67	19.50
Observations	3,003	2,021	318	664

Note: The data source is the Trajectories and Origins (TeO) dataset of 2008.

¹ The composition of work colleagues is conditional on employment and names of the respondents' children is conditional on having children. Thus, these variables are measured over restricted samples.

is a reasonable assumption because “unveiling” is a relatively rare phenomenon in France.²⁸

The results from these regressions overall confirm the findings obtained in the cross-sectional analysis. Indeed, the wearing of a conspicuous symbol is associated with a significant decline in economic participation. Once more, the estimated effect is much stronger when the individual always wears the symbol. The estimates are smaller in magnitude than those obtained in the cross-section, but are still statistically and economically significant. The results indicate that women who always veil are 20 percentage points less likely to be active than women not wearing any religious symbol in a given year. Other important determinants of the activity rate, as expected, are the number of young children, marital status, and the number of years of schooling. These results suggest that those obtained in Section 3.3.3 are not merely due to the timing of the survey and portray a more general phenomenon about Muslim women in France.

²⁸Two surveys conducted over (rather small) representative samples of the French Muslim population suggest that between 8 and 10 percent of women of Muslim faith declare having worn the veil in the past and are no longer doing so (IFOP 2019, [Institut Montaigne 2016](#)). Out of the total number of women not currently wearing the veil, this figure represents between 12.3% and 14.7%. Since here, we have both untreated individuals to which we assign treatment and treated individuals whom we assign to the untreated group, it is not clear in which direction this measurement error biases our estimates. In light of those issues, we treat this analysis simply as a robustness check of our main results obtained in the cross-section.

Table A.3: Effect of veiling on economic participation of adult Muslim women, retrospective panel data

This table shows the results of random-effects regression models of the economic activity dummy on the veiling status and other covariates in the retrospective panel dataset. Standard errors clustered at the individual level in parentheses. The estimation sample is restricted to adult Muslim women with no missing covariates and to time periods during which the individual was in France. In the last column, we estimate the specification in column (3) on the restricted sample of individuals aged at least 25 years old. Level of significance: * $p < 0.1$, ** $p < 0.05$, *** $p < 0.01$.

A.4 Plots for the tests of the four implications

In Figures A.1 to A.4 we present the results of the tests of Implications 1–4, respectively.

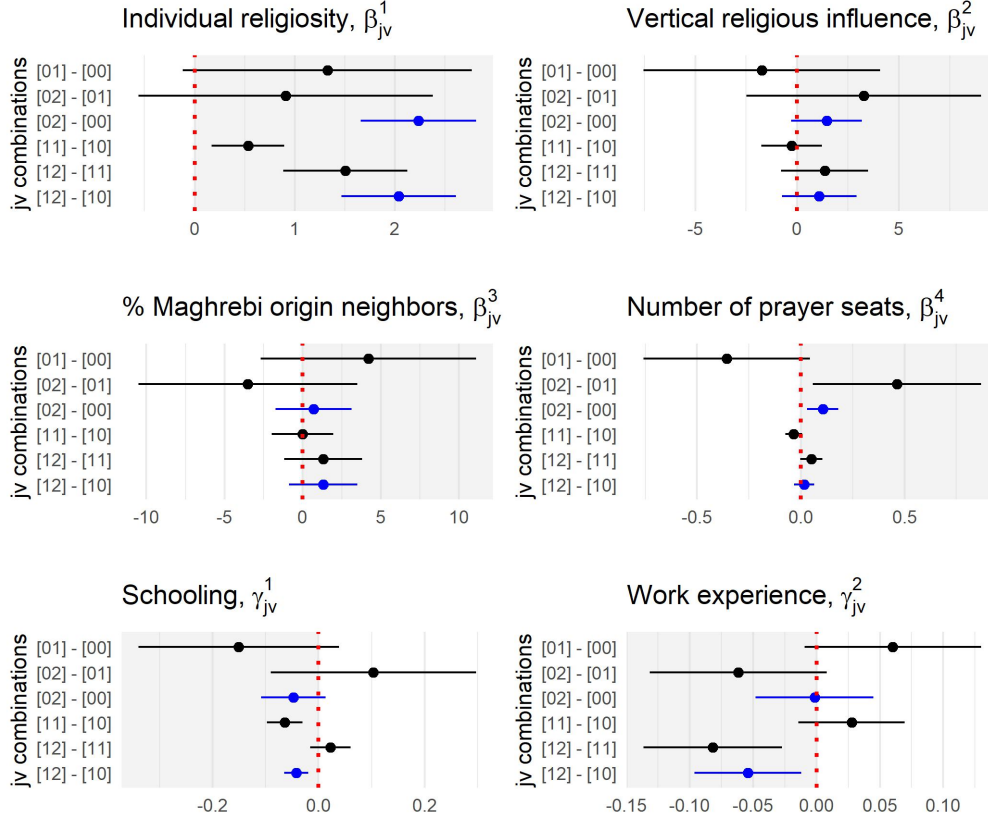

Figure A.1: Hypothesis tests for Implication 1. Shaded areas correspond to the region where estimates are predicted to fall. Vertical axis labels correspond to the combination of (j, v) alternatives (e.g. the first line of the top-left graph plots the estimate for $\beta_{01}^1 - \beta_{00}^1$). In blue: combinations which compare conspicuous symbol-wearing with no symbol-wearing. In black: combinations which include intermediate comparisons with discrete symbol-wearing. 95% confidence intervals are reported.

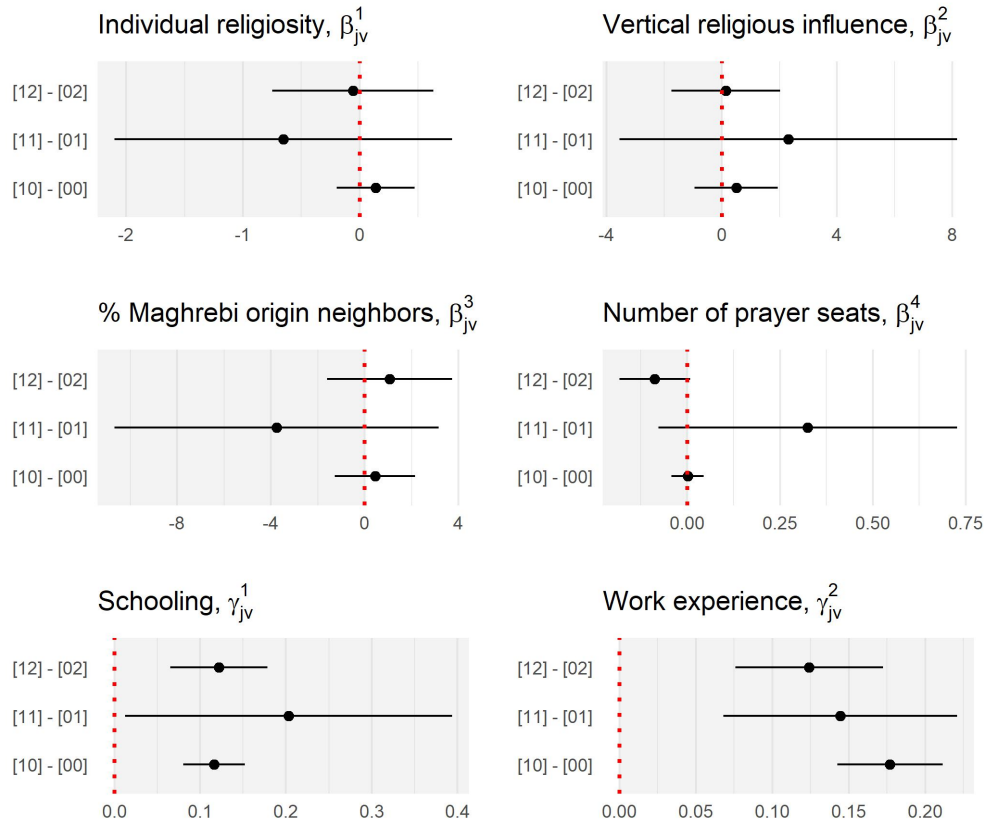

Figure A.2: Hypothesis tests for Implication 2. Shaded areas correspond to the region where estimates are predicted to fall. Vertical axis labels correspond to the combination of (j, v) alternatives (e.g. the first line of the top-left graph plots the estimate for $\beta_{12}^1 - \beta_{02}^1$). 95% confidence intervals are reported.

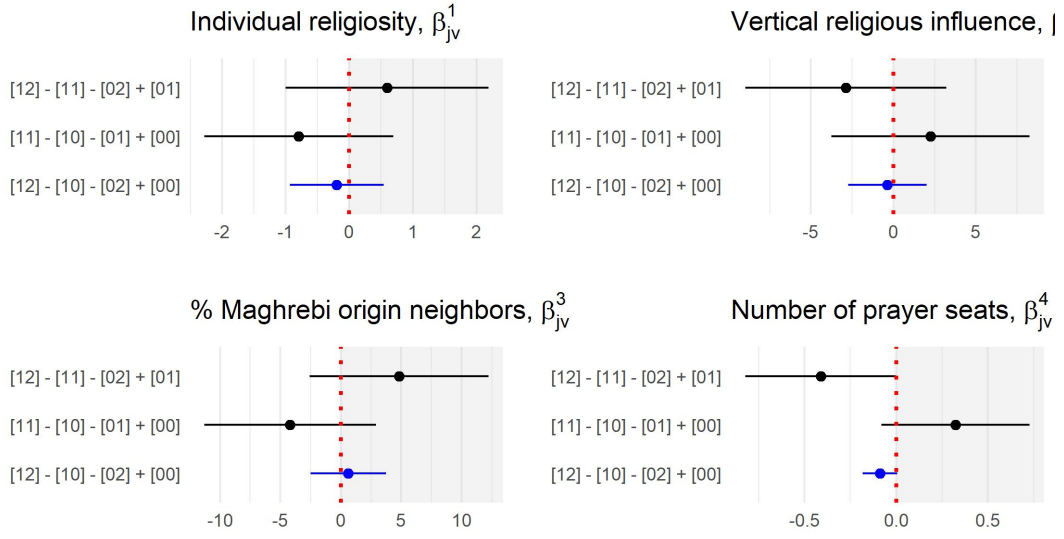

Figure A.3: Hypothesis tests for Implication 3: Religious motives channel. Shaded areas correspond to the region where estimates are predicted to fall. Vertical axis labels correspond to the combination of (j, v) alternatives (e.g. the first line of the top-left graph plots the estimate for $\beta_{12}^1 - \beta_{11}^1 - \beta_{02}^1 + \beta_{01}^1$). In blue: combinations which compare conspicuous symbol-wearing with no symbol-wearing. In black: combinations which include intermediate comparisons with discrete symbol-wearing. 95% confidence intervals are reported.

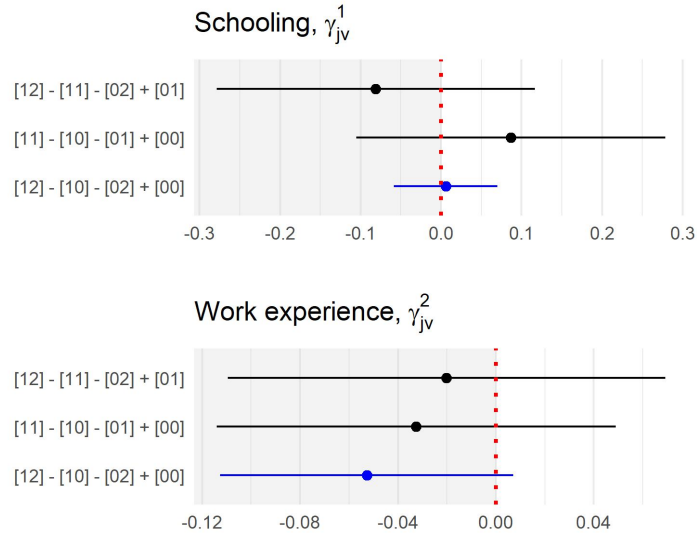

Figure A.4: Hypothesis tests for Implication 4: Economic discrimination channel. Shaded areas correspond to the region where estimates are predicted to fall. Vertical axis labels correspond to the combination of (j, v) alternatives (e.g. the first line of the top-left graph plots the estimate for $\beta_{12}^1 - \beta_{11}^1 - \beta_{02}^1 + \beta_{01}^1$). In blue: combinations which compare conspicuous symbol-wearing with no symbol-wearing. In black: combinations which include intermediate comparisons with discrete symbol-wearing. 95% confidence intervals are reported.

Observations	2,598					
Additional controls ¹	✓					
Pseudo R^2	0.224					

Note: This table reports estimates of the parameters of the econometric model (9). The baseline category is the choice of inactivity and not wearing any religious symbol. Individual religiosity and vertical religious pressures are measured as indices (with mean zero and variance 1) constructed from multiple proxies available in the TeO data (see Appendix A.1 for details). ShareMaghrebi _{i} is the proportion of the local population that is of Maghrebi origin. CapacityMosques _{i} is the estimated capacity in Muslim places of worship in the area of residence. Robust standard errors in parentheses. Point estimates in bold are significant at the 1% level ($p < 0.01$, * $p < 0.05$, + $p < 0.1$).

¹ Additional controls include age, age squared, marital status (a dummy for having a partner), a dummy equal to one if the partner is working, immigration status and a set of dummy variables for quintiles of the local (neighborhood-level) unemployment rate of immigrants.

Veiling Status; Dummies; Education; Work exp.	Table 2, col (6)	-0.171	-0.142	-0.127	-0.067

Notes: This Table reports bias-adjusted lower bounds of the coefficient on *Always conspicuous symbol* in our regression for the activity rate based on Oster (2019). Columns (1) to (4) report these lower bounds given by $\beta^* = \beta_F - \delta(\beta_R - \beta_F) \times (R^2_{max} - \hat{R}^2_F)/(\hat{R}^2_F - \hat{R}^2_R)$. β_F and \hat{R}^2_F are respectively our coefficient and the R-squared in a regression including our full set of controls (here, column 6 of Table 2); β_R and \hat{R}^2_R are respectively the coefficient and the R-squared obtained from a regression with a restricted set of controls; R^2_{max} is the R-squared from a regression that includes all observable and unobservable controls; δ is the extent of selection on unobservables relatively to the explanatory power of observables. Because $R^2_F = 0.531$, $\delta = 0.88$ corresponds to the case in which all the unexplained part of the activity rate is due to selection on unobservables (R^2 of 1). $\delta = 0.44$ is the case in which half of the unexplained variation in the activity rate is due to selection on unobservables. Column (5) shows the lower bound for $R^2_{max} = 1$ for illustrative purposes. In the real world, where there is significant measurement error, R^2_{max} should be lower than one (Gonzalez and Miguel 2015). The expression “Dummies” refers to full sets of birthyear, age of arrival in France, birthplace, and region of residence fixed effects.

B Veiling and economic outcomes in Turkey

In this Appendix, we explore the relationship between veiling and economic outcomes in Turkey and compare it to what we obtained for France and to that found by Shofia (2020) for Indonesia. Turkey is an interesting context to study veiling patterns since “it has long been considered a unique case of successful modernization through secularization” (Platteau 2017, p.355). Between the proclamation of the Turkish Republic, in October 1923, and the rise of the pro-Islamic conservative Justice and Development Party (AKP) to power in the early 2000s, the country was ruled by secular governments. The founders of the Republic implemented a top-down nationalist modernization project to “Westernize” Turkey. A major aspect of the multiple reforms adopted over the following decades was their secular nature as the government wanted to build a national identity that would subordinate the religious one (Sakalli 2019). Inspired by French State secularization, reforms ranging from the abolishment of the Caliphate to the adoption of Western dress codes profoundly changed the Turks’ religious life. The series of secular legislation included veil bans in the public sphere. The 1982 Turkish constitution regulates veiling for civil servants, requiring women to uncover their head while on duty. The ban on headscarves was then extended to all universities in Turkey in 1997. Those regulations stayed in effect until they were gradually repealed by AKP: in 2010 for university campuses; in 2013 for state institutions; in 2014 for high schools; in 2016 for policewomen; and in 2017 for female army officers (Corekcioglu 2021).

Given that, despite the secular modernization of Turkey, Islam is by far the most prominent religion in the country, we see Turkey as an intermediate case between France and Indonesia in our theoretical framework. Similar to France, women face legal disincentives to veil in public. However, like Indonesia, Turkey is a Muslim-majority country. Therefore, we would expect the correlation between veiling and economic outcomes in Turkey to mirror those differences. Specifically, we expect the correlation between veiling and economic participation to be *negative*, but lower in magnitude than what we see in France because most of the Turkish society is religious.

To study the patterns of veiling and economic participation, we use Turkish data compiled from multiple sources by Livny (2020).²⁹ Importantly, these data contain information on veiling practices in Turkey, which is available at the district level. We collapse the different types of veils (turban, hijab, and burka) so as to obtain a single measure of veiling rate in each district.

²⁹The data are publicly available on Avital Livny’s website (<https://www.alivny.com/data>).

For economic outcomes, so as to harmonize those variables with our measures of veiling that span the years 2010 to 2015, we take the average of the outcomes in the district (province for GDP per capita) over the same time period. In Figure B.1, we plot the relationship between the veiling rate and four measures of economic participation (female primary and secondary school completion, the female literacy rate, and GDP per capita) along with a quadratic fit.³⁰ For all of the outcomes we observe a negative association, suggesting that, in Turkey as in France, the veil might not act as an integration strategy. Interestingly, these negative relationships appear to be linear as most of the (small) curvature is driven by regions of the veiling-rate distribution with low mass (i.e. districts with low veiling rates).

We take these results as further suggestive evidence in line with the theory. The wearing of the veil was frowned upon by the secular elite before the bans were repealed, thus imposing a high cost to women when they veil and are economically active. Actually, as [Platteau \(2017\)](#) argues, the rise of an Islamist party to power reinforced the laicists' attachment to the secular values. Islamic symbols, such as the veil, were sometimes also seen as manifesting a political identity in the public sphere in an increasingly polarized political context. Thus, even if Turkey is a Muslim-majority country, we find that the positive correlation documented by [Shofia \(2020\)](#) in Indonesia does not hold in this data. This suggests that her results regarding veiling behavior and economic participation are context-specific. Viewed through the lens of our theoretical framework, such a correlation can hold in Indonesia only because of two concomitant factors: (1) Indonesia is a Muslim-majority country, and (2) the veil is not subject to social or legal disapproval.

³⁰For robustness, we also checked whether this relationship could be driven by religiosity of the district. We produced similar plots in which we control for religiosity and find very similar conclusions. Results are available upon request.

Figure B.1: Relationship between veiling and economic outcomes at district level, Turkey 2010–2015

(a) Primary school completion

(b) Secondary school completion

(c) Literacy

(d) GDP per capita

Note: The data source is [Livny \(2020\)](#). These figures plot the relationship between the veiling rate in a district in 2010–2015 and the average of an economic outcome in that district over the same period, along with a quadratic fit and 95% confidence bands. For GDP per capita, the dependent variable is measured at the province level.

C Discreet symbols and economic penalties to veiling

In Section 3.3 we discussed how in our data, discreet symbols are worn Muslim women who are younger, educated, economically active, and moderately religious. In this appendix we discuss how our model from Section 4 can rationalize this pattern.

To do so, we consider a simplified version of the model presented in Section 4. We assume that $p_0 = 0$ (no socio-religious penalty if choosing not to work) and $m_0 = 0$ (no material benefit if choosing not to work). Furthermore, here we depart slightly from the modelling of the economic motives in Section 4.3 by assuming that the effective wage is concave in v : $(1 - \pi(v))w$, where the function $\pi(v)$ is a convex function of v . This differs from Section 4.3, where we assume that the effective wage is $(1 - v)w$. By assuming that the effective wage is concave in v , and not linear, we essentially want to model the fact that discrimination against conspicuous religious symbols is disproportionately large in the labor market, compared to that against discreet symbols. This assumption reflects the observed attitudes against veiling (see our description of the context of veiling in France), as well as French policies which explicitly ban the wearing of conspicuous religious symbols for several professions (notably for civil servants) but allows the wearing of discreet symbols.

Finally, we assume away the “physical” cost of veiling from the main model: $c(v) = 0$. This is purely for simplicity, since the convexity of the function π makes the cost $c(v)$ redundant to obtain the main intuition of this model extension.

With these assumptions, the condition (3) for a woman to choose to work over not working rewrites as

$$-p_1(r + R)(1 - v_1^*) - (1 - \pi(v_1^*))w > 0,$$

which simply means that the utility obtained when she adopts her optimal level of veiling at work v_1^* must surpass the utility of not working (here 0). Isolating the terms which depend on v_1^* on one side, and the constants on the other, we obtain

$$p_1(r + R)v_1^* - w\pi(v_1^*) > p_1(r + R) - w. \quad (13)$$

Recall that v_1^* is an endogenous choice which depends on $r + R$ and w , so it is not immediately obvious how the left-hand term varies with $r + R$ and w , and therefore when this condition is satisfied.

In Figure C.1 we plot this left-hand term, along with the right-hand constant, for different values of $r + R$ and w , and by assuming a quadratic $\pi(v)$. We consider four profiles which combine low and high values for the religiosity $r + R$ and the wage w : (a) low religiosity, low wage, (b) high religiosity, low wage, (c) low religiosity, high wage, (d) high religiosity, high wage. In this graph, we observe that the two profiles (a) and (d) both choose to work, and adopt a similarly low veiling strategy. Profile (d) in particular fits the description of the young, educated, economically active, and moderately religious women who wear discreet symbols in our data. On the other hand, profile (b) chooses not to work (but would adopt a high level of veiling if she did), and profile (c) chooses to work and a negligible level of veiling.

To conclude, the adoption of discreet religious symbols by moderately religious but educated Muslim women could be explained by the fact that economic discrimination disproportionately targets conspicuous symbols. Hence, wearing discreet symbols might operate as a tool for economic integration in the face of strong economic costs of veiling.

Appendix References

Agrikoliansky, Éric. *Les partis politiques en France-3e éd.* Armand Colin, 2016.

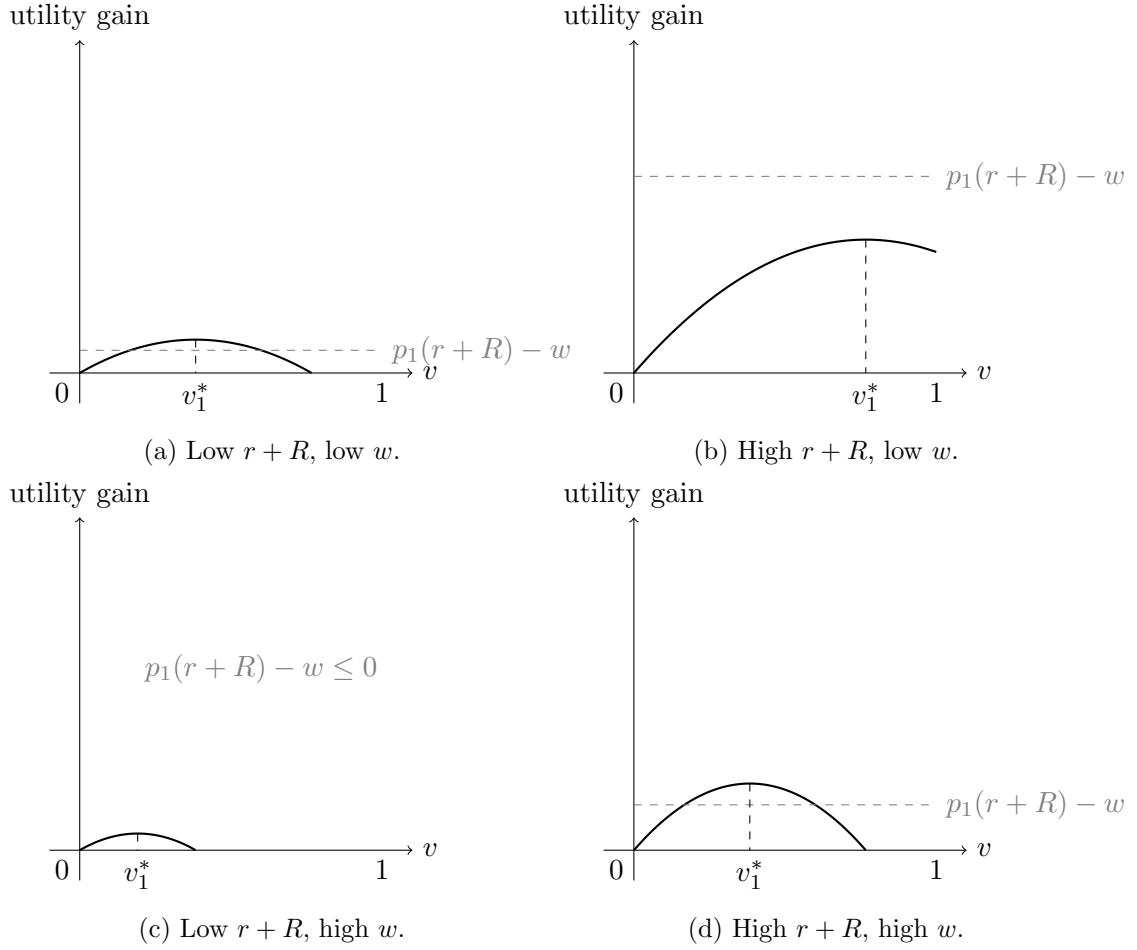

Figure C.1: Utility gains from veiling, $p_1(r + R)v - w\pi(v)$, as a function of v for different religiosity and wage profiles. The woman chooses to work if the utility gain from veiling at v_1^* (here, the top of the parabola) is greater than $p_1(r + R) - w$. For the convex function π , we consider a quadratic form $\pi(v) = av^2$. Values used to generate the graphs: $p = .5$, low $r + R = 1.15$, high $r + R = 2.3$, low $w = .5$, high $w = 1$, $a = 1.5$.
